

Inferential Statistics

Module : Inferential Statistics

Instructor: Dr. Darshan Ingle

What you'll learn

- 1 Probability
 - 2 Random Variable
 - 3 Binomial Distribution
 - 4 Normal Distribution
 - 5 PDF vs CDF
 - 6 Standard Score
 - 7 CLT and Baye's Theorem
- } fast

- Many events can't be predicted with total certainty. The best we can say is how **likely** they are to happen, using the idea of probability.
- Tossing a Coin

H / T

$$H = \frac{1}{2} \quad P(H) = 0.5$$

$$T = \frac{1}{2} \quad -\text{---}$$

- Throwing Dice

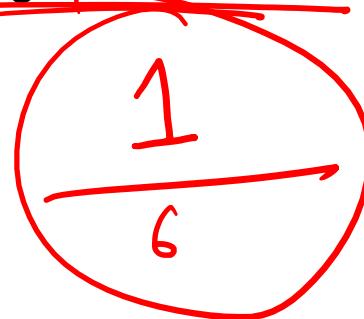

1, 2, 3, 4, 5, 6

- In general:

$$\text{Probability of an event happening} = \frac{\text{Number of ways it can happen}}{\text{Total number of outcomes}} = \frac{1}{6}$$

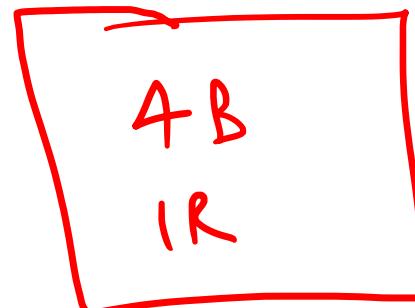

- Example: the chances of rolling a "4" with a die

- In general:

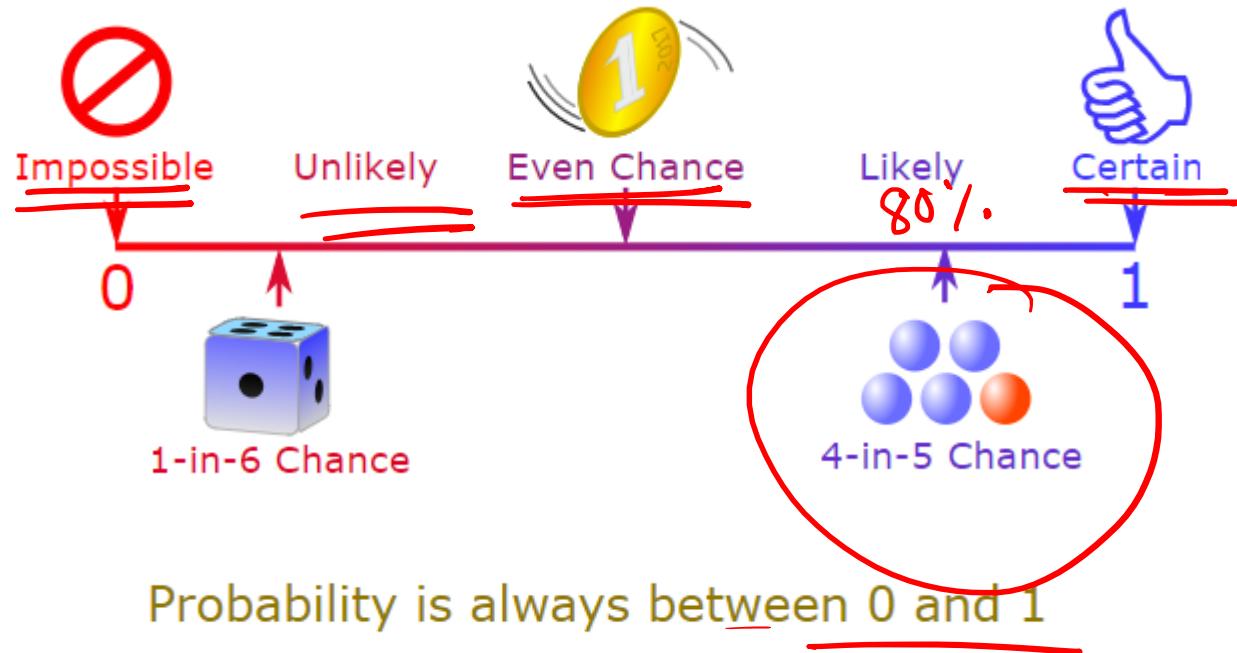

$$\text{Probability of an event happening} = \frac{\text{Number of ways it can happen}}{\text{Total number of outcomes}} = \frac{4}{5}$$

- Example: there are 5 marbles in a bag: 4 are blue, and 1 is red. What is the probability that a blue marble gets picked? $= 0.8$

Probability Line

- Summary:

- **Experiment:** a repeatable procedure with a set of possible results.
- Example: Throwing dice

$$\{1, 2, 3, 4, 5, 6\}$$

Probability

- **Outcome:** A possible result of an experiment.
- Example: Getting a "6"

6

- **Sample Space:** all the possible outcomes of an experiment.
- Example: choosing a card from a deck

There are 52 cards in a deck (not including Jokers)

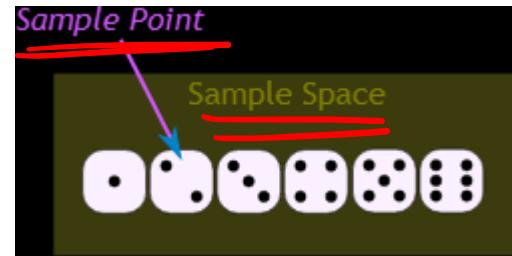

So the **Sample Space is all 52 possible cards:** {Ace of Hearts, 2 of Hearts, etc... }

- The Sample Space is made up of Sample Points:
- **Sample Point:** just one of the possible outcomes
- Example: Deck of Cards

- the 5 of Clubs is a sample point
- the King of Hearts is a sample point

"King" is not a sample point. There are 4 Kings, so that is 4 *different* sample points.

- Example: Throwing dice
- There are 6 different sample points in the sample space.

- Event: one or more outcomes of an experiment
- Example Events:
- An event can be just one outcome:
 - Getting a Tail when tossing a coin
 - Rolling a "5"
- An event can include more than one outcome:
 - Choosing a "King" from a deck of cards (any of the 4 Kings)
 - Rolling an "even number" (2, 4 or 6)
piece

- Example: Alex wants to see how many times a "double" comes up when throwing 2 dice.

- The **Sample Space** is all possible **Outcomes** (36 Sample Points):

- $\{1,1\} \{1,2\} \{1,3\} \{1,4\} \dots \{6,3\} \{6,4\} \{6,5\} \{6,6\}$

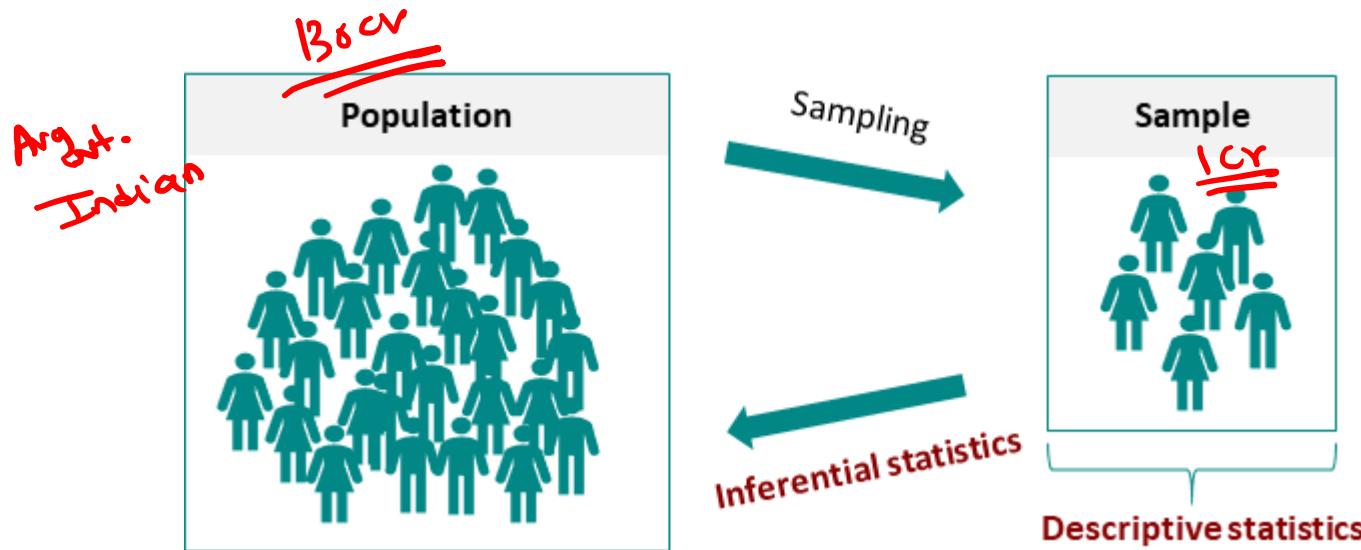

- The **Event** Alex is looking for is a "double", where both dice have the same number. It is made up of these **6 Sample Points**:

- $\{1,1\} \{2,2\} \{3,3\} \{4,4\} \{5,5\} \text{ and } \{6,6\}$

6 times

Descriptive vs. Inferential statistics

upGrad

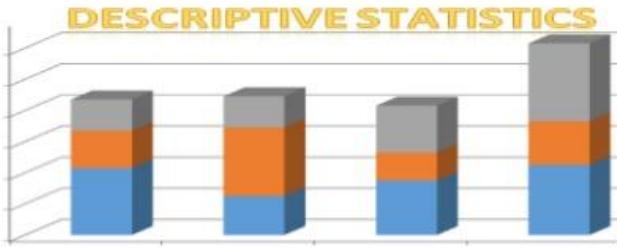

Descriptive vs. Inferential statistics

Mean | Mode | Median

S. No	Descriptive Statistics	Inferential Statistics
1	Concerned with the describing the target population	Make <u>inferences from the sample</u> and <u>generalize them to the population</u> .
2	Organize, analyze and present the data in a meaningful manner	<u>Compares, test and predicts future outcomes.</u>
3	Final results are shown in form of charts, tables and Graphs	Final result is the <u>probability scores</u> .
4	Describes the data which is already known	Tries to make <u>conclusions about the population</u> that is <u>beyond the data available</u> .
5	Tools- Measures of central tendency (mean/median/ mode), Spread of data (range, standard deviation etc.)	Tools- <u>hypothesis tests</u> , <u>Analysis of variance</u> etc. ANOVA

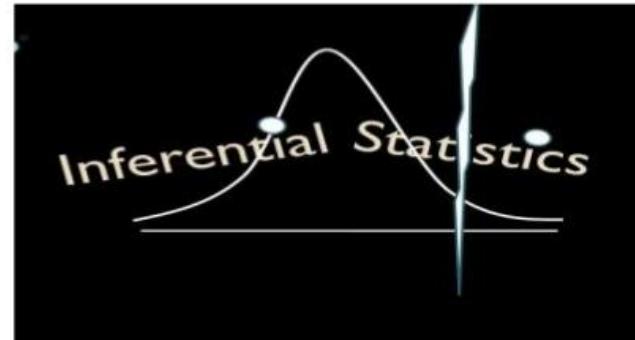

Descriptive Statistics

Descriptive statistics are numbers that are used to summarize and describe data. The word "data" refers to the information that has been collected from an experiment, a survey, a historical record, etc.

Inferential Statistics

The sample is a set of data taken from the population to represent the population. Probability distributions, hypothesis testing, correlation testing and regression analysis all fall under the category of **inferential statistics**.

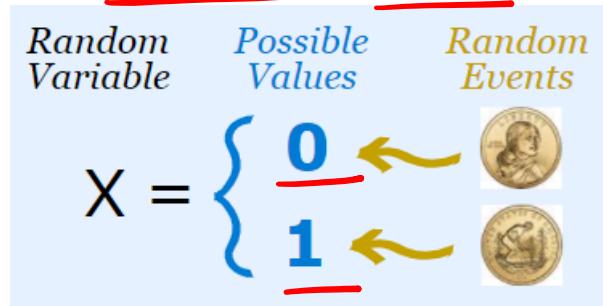

Statistics vs Probability

Statistics	Probability
It deals with a <u>sample of data</u> .	It deals with a <u>model of random data</u> .
It infers information about a population or a random process that produced a sample.	It deduces information about random events or samples produced from a model.

Random Variables

- A Random Variable is a set of possible values from a random experiment.
- Example: Tossing a coin: we could get Heads or Tails.
- Let's give them the values Heads=0 and Tails=1 and we have a Random Variable

"X":

In short:

$$\underline{\underline{X = \{0, 1\}}}$$

- Not Like an Algebra Variable

eg: $x + 2 = 6$

$x = 4$

{ R.V. has a whole set of values.
it can take any of those randomly.

eg: $X = \{0, 1, 2, 3\}$ Sample Space.

X can be 0, 1, 2, 3 randomly.

Random Variables

- **Sample Space**
- A Random Variable's set of values is the Sample Space.
- Example: Throw a die once
- Random Variable X = "The score shown on the top face".

X can be $1, 2, 3, 4, 5, 6$

$SS = \{ 1, 2, 3, 4, 5, 6 \}$

Random Variables

Example: How many heads when we toss 3 coins?

X = "The number of Heads" is the Random Variable.

In this case, there could be 0 Heads (if all the coins land Tails up), 1 Head, 2 Heads or 3 Heads.

So the Sample Space = {0, 1, 2, 3}

But this time the outcomes are NOT all equally likely.

The three coins can land in eight possible ways:

Looking at the table we see just 1 case of Three Heads, but 3 cases of Two Heads, 3 cases of One Head, and 1 case of Zero Heads. So:

- $P(X = 3) = 1/8$
- $P(X = 2) = 3/8$
- $P(X = 1) = 3/8$
- $P(X = 0) = 1/8$

$X =$ "Number of Heads"	3
HHH	Three quarters are shown, all showing George Washington's profile (heads).
HHT	Two quarters show George Washington's profile (heads), one shows a scene from the Lincoln Memorial (tails).
HTH	One quarter shows George Washington's profile (heads), two show a scene from the Lincoln Memorial (tails).
HTT	Two quarters show a scene from the Lincoln Memorial (tails), one shows George Washington's profile (heads).
THH	One quarter shows George Washington's profile (heads), two show a scene from the Lincoln Memorial (tails).
THT	Two quarters show a scene from the Lincoln Memorial (tails), one shows George Washington's profile (heads).
TTH	One quarter shows George Washington's profile (heads), two show a scene from the Lincoln Memorial (tails).
TTT	Three quarters are shown, all showing a scene from the Lincoln Memorial (tails).

Random Variables

- Example: Two dice are tossed.
- The Random Variable is $X = \text{"The sum of the scores on the two dice"}$.

Let's make a table of all possible values:

		1st Die					
		1	2	3	4	5	6
2nd Die	1	2	3	4	5	6	7
	2	3	4	5	6	7	8
	3	4	5	6	7	8	9
	4	5	6	7	8	9	10
	5	6	7	8	9	10	11
	6	7	8	9	10	11	12

There are $6 \times 6 = 36$ possible outcomes, and the Sample Space (which is the sum of the scores on the two dice) is $\{2, 3, 4, 5, 6, 7, 8, 9, 10, 11, 12\}$

Let's count how often each value occurs, and work out the probabilities:

- 2 occurs just once, so $P(X = 2) = 1/36$
- 3 occurs twice, so $P(X = 3) = 2/36 = 1/18$
- 4 occurs three times, so $P(X = 4) = 3/36 = 1/12$
- 5 occurs four times, so $P(X = 5) = 4/36 = 1/9$
- 6 occurs five times, so $P(X = 6) = 5/36$
- 7 occurs six times, so $P(X = 7) = 6/36 = 1/6$
- 8 occurs five times, so $P(X = 8) = 5/36$
- 9 occurs four times, so $P(X = 9) = 4/36 = 1/9$
- 10 occurs three times, so $P(X = 10) = 3/36 = 1/12$
- 11 occurs twice, so $P(X = 11) = 2/36 = 1/18$
- 12 occurs just once, so $P(X = 12) = 1/36$

7

Probability Distribution

upGrad

- A probability distribution is a table or an equation that links each outcome of a statistical experiment with its probability of occurrence.
 - Example to study relationship between random variables and probability distributions.
 - Suppose you flip a coin two times.
 - We get four possible outcomes: HH, HT, TH, and TT.
 - Now, let the variable X represent the number of Heads that result from this experiment.
 - The variable X can take on the values 0, 1, or 2.
 - In this example, X is a random variable; because its value is determined by the outcome of a statistical experiment.
- Total Outcomes = 4*
- $\#H=2, \{HH, HT, TH, TT\}$
- $X = \{0, 1, 2\}$

Number of heads	Probability
0	$\frac{1}{4} = 0.25$
1	$\frac{2}{4} = 0.50$
2	$\frac{1}{4} = 0.25$

The table represents the probability distribution of the random variable X.

Cumulative Probability Distributions

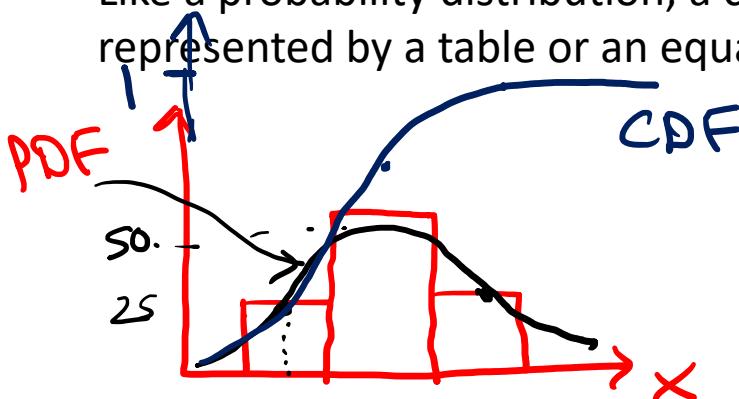

$$P(X \leq 1) = P(X = 1) + P(X = 0) + \cancel{P(X = 2)} + \cancel{P(X = 3)}$$

- A cumulative probability refers to the probability that the value of a random variable falls within a specified range.
- Example: Coin flip experiment. If we flip a coin two times, we might ask:
- What is the probability that the coin flips would result in one or fewer heads?
- The answer would be a cumulative probability.

$$P(X \leq 1) = P(X = 0) + P(X = 1) = 0.25 + 0.50 = 0.75$$

There is 75% that we flip a coin & we get one or less than one head.

- Like a probability distribution, a cumulative probability distribution can be represented by a table or an equation.

Number of heads: x	Probability: $P(X = x)$	Cumulative Probability: $P(X \leq x)$
0	0.25	0.25
1	0.50	0.75
2	0.25	1.00

- The simplest probability distribution occurs when all of the values of a random variable occur with equal probability. This probability distribution is called the uniform distribution.

Uniform Distribution. Suppose the random variable X can assume k different values. Suppose also that the $P(X = x_k)$ is constant. Then,

$$P(X = x_k) = 1/k$$

Example 1

Suppose a die is tossed. What is the probability that the die will land on 5?

$$S = \{1, 2, 3, 4, 5, 6\}$$

$$P(X=5) = \frac{1}{6}$$

Uniform Probability Distribution

upGrad

Example 2

$$P(X < 5)$$

Suppose we repeat the dice tossing experiment described in Example 1. This time, we ask what is the probability that the die will land on a number that is smaller than 5?

$$S = \{1, 2, 3, 4, 5, 6\}$$

each possible outcome is equally likely to occur.
∴ we hv. Uniform Distribution.

$$\begin{aligned} P(X < 5) &= P(X=1) + P(X=2) + P(X=3) + P(X=4) \\ &= \frac{1}{6} + \frac{1}{6} + \frac{1}{6} + \frac{1}{6} = \frac{4}{6} = \frac{2}{3}. \end{aligned}$$

- The expected value (EV) is an anticipated value for an investment at some point in the future.
- In statistics and probability analysis, the expected value is calculated by multiplying each of the possible outcomes by the likelihood each outcome will occur and then summing all of those values.
- By calculating expected values, investors can choose the scenario most likely to give the desired outcome.

$$EV = \sum P(X_i) \times X_i$$

- **Example:** Consider a normal six-sided die. Once you roll the die, it has an equal one-sixth chance of landing on one, two, three, four, five, or six. Given this information, the calculation is straightforward:

$$\left(\frac{1}{6} \times 1\right) + \left(\frac{1}{6} \times 2\right) + \left(\frac{1}{6} \times 3\right) \\ + \left(\frac{1}{6} \times 4\right) + \left(\frac{1}{6} \times 5\right) + \left(\frac{1}{6} \times 6\right) = 3.5$$

- If you were to roll a six-sided die an infinite amount of times, you see the average value equals 3.5.

- The expected value of a variable may fail your analysis, as it works the best for large-sized data.
- The value can be affected by the presence of outliers; therefore, you need to have a measure that analyses the risk involved in the analysis. This measure is the standard deviation of the variable.
- The standard deviation of a random variable is simply the standard deviation of a sample as it goes to infinity.
- It is denoted by ' σ '.
- Some additional points related to the standard deviation of the variable are as follows:
- Variance = $\text{Var}(X) = \sum(X - \mu)^2 p(X)$
- In other words, the variance is the expected value of the squared difference of the random variable X and the expected value m.
- **Standard deviation (σ) = $\sqrt{\text{Var}(X)}$**

Robert's work schedule for next week will be released today. Robert will work either 45, 40, 25, or 20.8 hours. The probabilities for each possibility are listed below:

45 hours: 0.3

40 hours: 0.2

25 hours: 0.4

20.8 hours: 0.1

What is the standard deviation of the possible outcomes?

There are four steps to finding the standard deviation of random variables.

1. First, calculate the mean of the random variables.
2. Second, for each value in the group (45, 40, 25, and 20.8), subtract the mean from each and multiply the result by the probability of that outcome occurring.
3. Third, add the four results together.
4. Fourth, find the square root of the result.

Standard Deviation of a Random Variable

upGrad

Robert's work schedule for next week will be released today. Robert will work either 45, 40, 25, or 20.8 hours. The probabilities for each possibility are listed below:

45 hours: 0.3

40 hours: 0.2

25 hours: 0.4

20.8 hours: 0.1

What is the standard deviation of the possible outcomes?

$$(45 - 32.7)^2(0.3) = 45.38$$

$$(40 - 32.7)^2(0.2) = 10.66$$

$$(25 - 32.7)^2(0.4) = 23.72$$

$$(12 - 32.7)^2(0.1) = 42.85$$

$$45.38 + 10.66 + 23.72 + 42.85 = 122.61$$

$$\sqrt{122.61} = 11.07$$

Discrete Probability Distributions

Addition Rule 1: When two events, A and B, are mutually exclusive, the probability that A or B will occur is the sum of the probability of each event.

$$P(A \text{ or } B) = P(A) + P(B)$$

Addition Rules for Probability

Experiment: A single 6-sided die is rolled.
What is the probability of rolling a 2 or a 5?

Addition Rules for Probability

upGrad

Experiment 2: A spinner has 4 equal sectors colored yellow, blue, green, and red.

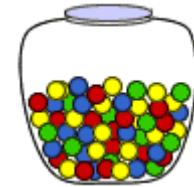

What is the probability of landing on red or blue after spinning this spinner?

Addition Rules for Probability

Experiment 3: A glass jar contains 1 red, 3 green, 2 blue, and 4 yellow marbles.

If a single marble is chosen at random from the jar, what is the probability that it is yellow or green?

Addition Rules for Probability

- In each of the three experiments before, the events are mutually exclusive.
- Let's look at some experiments in which the events are non-mutually exclusive.
- **Experiment 4:** A single card is chosen at random from a standard deck of 52 playing cards. What is the probability of choosing a king or a club?

Additional Rule 2: When two events, A and B, are non-mutually exclusive, the probability that A or B will occur is:

$$P(A \text{ or } B) = P(A) + P(B) - P(A \text{ and } B)$$

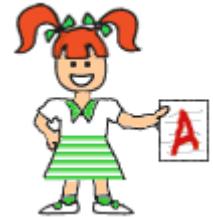

Addition Rules for Probability

- **Experiment 4:** A single card is chosen at random from a standard deck of 52 playing cards. What is the probability of choosing a king or a club?

Addition Rules for Probability

- **Experiment 5:** In a math class of 30 students, 17 are boys and 13 are girls. On a unit test, 4 boys and 5 girls made an A grade.
- If a student is chosen at random from the class, what is the probability of choosing a girl or an A student?

- **Definition:** Two events, A and B, are **independent** if the fact that A occurs does not affect the probability of B occurring.

Eg:

- Landing on heads after tossing a coin AND rolling a 5 on a single 6-sided die.
- Choosing a marble from a jar AND landing on heads after tossing a coin.
- Choosing a 3 from a deck of cards, replacing it, AND then choosing an ace as the second card.
- Rolling a 4 on a single 6-sided die, AND then rolling a 1 on a second roll of the die.

Multiplication Rule 1: When two events, A and B, are independent, the probability of both occurring is:

$$P(A \text{ and } B) = P(A) \cdot P(B)$$

- **Experiment 1:** A dresser drawer contains one pair of socks with each of the following colors: blue, brown, red, white and black. Each pair is folded together in a matching set. You reach into the sock drawer and choose a pair of socks without looking. You replace this pair and then choose another pair of socks. What is the probability that you will choose the red pair of socks both times?

- **Experiment 2:** A coin is tossed and a single 6-sided die is rolled. Find the probability of landing on the head side of the coin and rolling a 3 on the die.

Combinations Formula:

upGrad

$$C(n, r) = \frac{n!}{(r!(n - r)!)}$$

For $n \geq r \geq 0$.

Combinations Formula:

$$C(n, r) = \frac{n!}{(r!(n - r)!)}$$

upGrad

Combination Problem 1

Choose 2 Prizes from a Set of 6 Prizes

You have won first place in a contest and are allowed to choose 2 prizes from a table that has 6 prizes numbered 1 through 6. How many different combinations of 2 prizes could you possibly choose?

- In this example, we are taking a subset of 2 prizes (r) from a larger set of 6 prizes (n). Looking at the formula, we must calculate “6 choose 2.”
- $C(6,2) = 6!/(2! * (6-2)!) = 6!/(2! * 4!) = 15$ Possible Prize Combinations
- The 15 potential combinations are {1,2}, {1,3}, {1,4}, {1,5}, {1,6}, {2,3}, {2,4}, {2,5}, {2,6}, {3,4}, {3,5}, {3,6}, {4,5}, {4,6}, {5,6}

Combinations Formula:

$$C(n, r) = \frac{n!}{(r!(n - r)!)}$$

upGrad

Combination Problem 2 Choose 3 Students from a Class of 25

A teacher is going to choose 3 students from her class to compete in the spelling bee. She wants to figure out how many unique teams of 3 can be created from her class of 25.

In this example, we are taking a subset of 3 students (r) from a larger set of 25 students (n). Looking at the formula, we must calculate "25 choose 3."

$$C(25,3) = 25!/(3! * (25-3)!) = 2,300 \text{ Possible Teams}$$

Binomial Probability Distribution

A **binomial experiment** is a statistical experiment that has the following properties:

1. The experiment consists of n repeated trials.
2. Each trial can result in just two possible outcomes. We call one of these outcomes a success and the other, a failure.
3. The probability of success, denoted by P , is the same on every trial.
4. The trials are independent; that is, the outcome on one trial does not affect the outcome on other trials.

Consider the following statistical experiment. You flip a coin 2 times and count the number of times the coin lands on heads. This is a binomial experiment because:

1. The experiment consists of repeated trials. We flip a coin 2 times.
2. Each trial can result in just two possible outcomes - heads or tails.
3. The probability of success is constant - 0.5 on every trial.
4. The trials are independent; that is, getting heads on one trial does not affect whether we get heads on other trials.

Notation

The following notation is helpful, when we talk about binomial probability.

- x : The number of successes that result from the binomial experiment.
- n : The number of trials in the binomial experiment.
- P : The probability of success on an individual trial.
- Q : The probability of failure on an individual trial. (This is equal to $1 - P$.)
- $n!$: The factorial of n (also known as n factorial).
- $b(x; n, P)$: Binomial probability - the probability that an n -trial binomial experiment results in exactly x successes, when the probability of success on an individual trial is P .
- ${}_n C_r$: The number of combinations of n things, taken r at a time.

Binomial Probability Distribution

upGrad

Binomial Formula. Suppose a binomial experiment consists of n trials and results in x successes. If the probability of success on an individual trial is P , then the binomial probability is:

$$b(x; n, P) = \frac{n!}{x!(n-x)!} \cdot P^x \cdot (1 - P)^{n-x}$$

or

$$b(x; n, P) = \frac{n!}{x!(n-x)!} \cdot P^x \cdot (1 - P)^{n-x}$$

$$n!_x = \frac{n!}{x!(n-x)!}$$

Binomial Probability Distribution

upGrad

Example 1

Suppose a die is tossed 5 times. What is the probability of getting exactly 2 fours?

Solution: This is a binomial experiment in which the number of trials is equal to 5, the number of successes is equal to 2, and the probability of success on a single trial is $1/6$ or about 0.167. Therefore, the binomial probability is:

$$= \frac{n!}{x!(n-x)!} \cdot p^x \cdot (1-p)^{n-x}$$

$$b(2; 5, 0.167) = {}_5C_2 * (0.167)^2 * (0.833)^3$$

$$\bar{x} \bar{n} \bar{P} b(2; 5, 0.167) = 0.161$$

$$P = \frac{1}{6} = 0.167$$

Cumulative Binomial Probability

upGrad

~~P(X <= 5)~~

A **cumulative binomial probability** refers to the probability that the binomial random variable falls within a specified range (e.g., is greater than or equal to a stated lower limit and less than or equal to a stated upper limit).

Example 2

The probability that a student is accepted to a prestigious college is 0.3. If 5 students from the same school apply, what is the probability that at most 2 are accepted?

$$p = 0.3, n = 5$$

$$x \leq 2$$

Solution: To solve this problem, we compute 3 individual probabilities, using the binomial formula. The sum of all these probabilities is the answer we seek. Thus,

$$b(x \leq 2; 5, 0.3) = b(x = 0; 5, 0.3) + b(x = 1; 5, 0.3) + b(x = 2; 5, 0.3)$$

$$b(x \leq 2; 5, 0.3) = 0.1681 + 0.3601 + 0.3087$$

$$b(x \leq 2; 5, 0.3) = 0.8369$$

- The Standard Deviation is a measure of how spread out numbers are.
- Its symbol is σ (the greek letter sigma)
- The formula is easy: it is the **square root** of the **Variance**. So now you ask, "What is the Variance?"

- The Variance is defined as:

The average of the **squared** differences from the Mean.

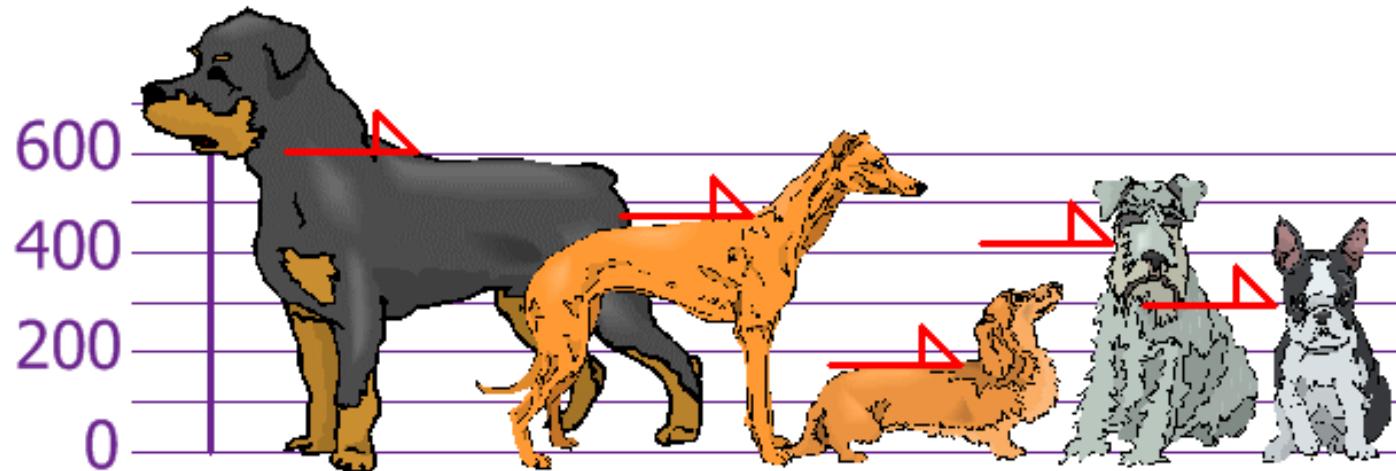

- To calculate the variance follow these steps:

- Work out the Mean

- Then for each number: subtract the Mean and square the result
- Then work out the average of those squared differences.

Example

- You and your friends have just measured the heights of your dogs (in millimeters):

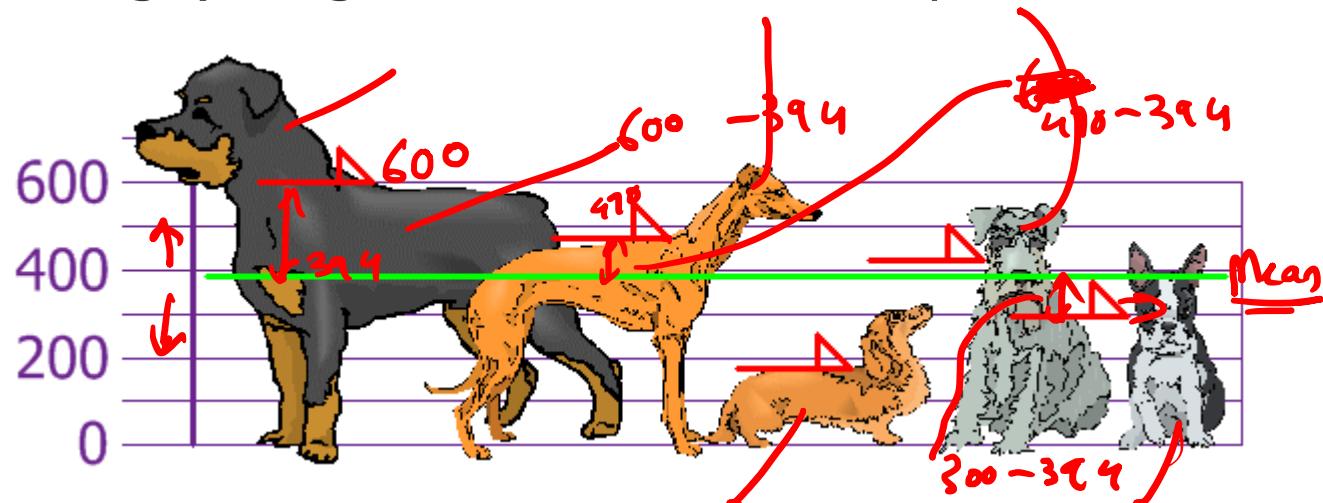

- The heights (at the shoulders) are: 600mm, 470mm, 170mm, 430mm and 300mm.
- Find out the Mean, the Variance, and the Standard Deviation.

Example

$$\begin{aligned}\text{Mean} &= \frac{600 + 470 + 170 + 430 + 300}{5} \\ &= \frac{1970}{5} \\ &= 394\end{aligned}$$

- so the mean (average) height is 394 mm. Let's plot this on the chart:

Variance

$$\begin{aligned}\sigma^2 &= \frac{206^2 + 76^2 + (-224)^2 + 36^2 + (-94)^2}{5} \\&= \frac{42436 + 5776 + 50176 + 1296 + 8836}{5} \\&= \frac{108520}{5} \\&= 21704\end{aligned}$$

- So the Variance is **21,704**

- And the Standard Deviation is just the square root of Variance, so:
- Standard Deviation

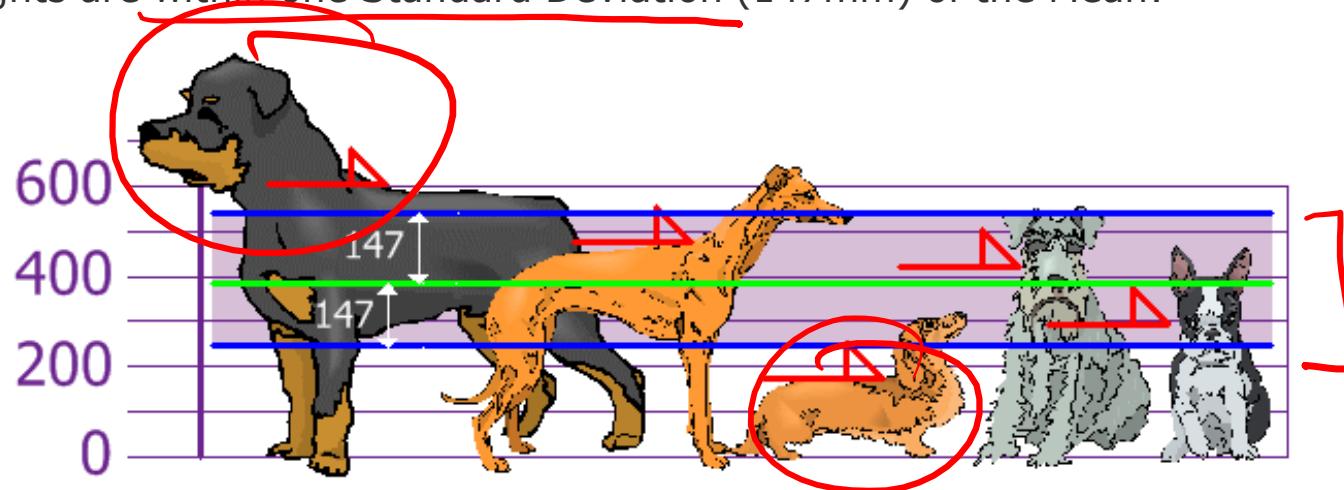

$$\sigma = \sqrt{21704}$$

$$= 147.32\dots$$

$$= \underline{\underline{147}} \text{ (to the nearest mm)}$$

Example

- And the good thing about the Standard Deviation is that it is useful. Now we can show which heights are within one Standard Deviation (147mm) of the Mean:

- So, using the Standard Deviation we have a "standard" way of knowing what is normal, and what is extra large or extra small.
- Rottweilers **are** tall dogs. And Dachshunds **are** a bit short, right?

The "Population Standard Deviation": $\sigma = \sqrt{\frac{1}{N} \sum_{i=1}^N (x_i - \mu)^2}$

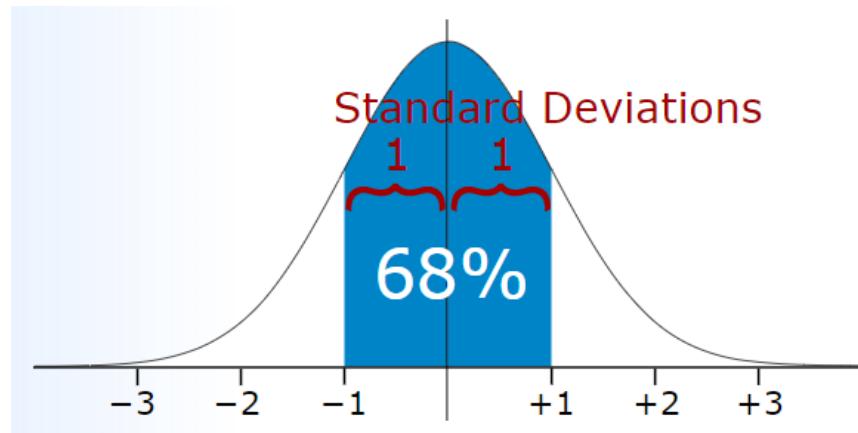

The "Sample Standard Deviation": $s = \sqrt{\frac{1}{N-1} \sum_{i=1}^N (x_i - \bar{x})^2}$

jagged /
adjustment

- Looks complicated, but the important change is to divide by **N-1** (instead of **N**) when calculating a Sample Variance.

Range of Standard Deviation

- We can expect about 68% of values to be within plus-or-minus 1 standard deviation.

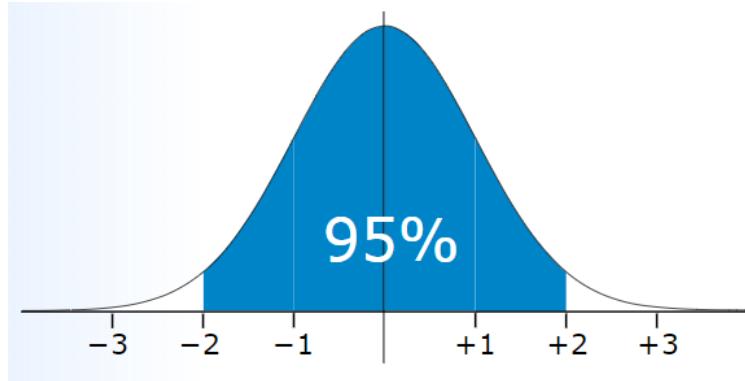

68% : $394 \pm 1 \cdot (147)$

95% : $394 \pm 2 \cdot (147)$

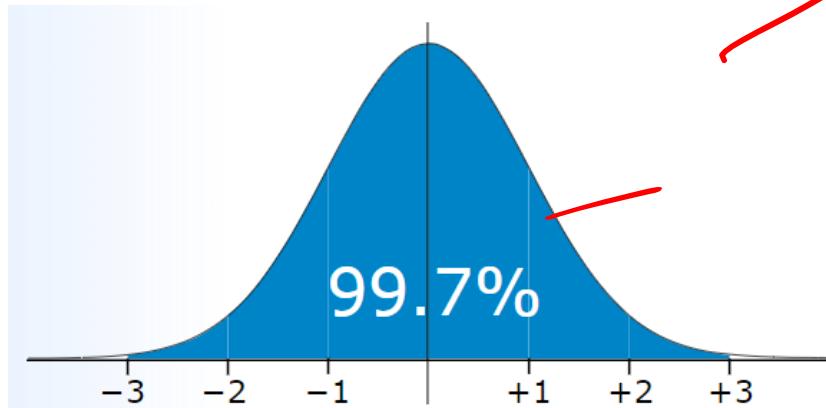

99.7% : $394 \pm 3 \cdot (147)$

68% of values are within
1 standard deviation of the mean

Range of Standard Deviation

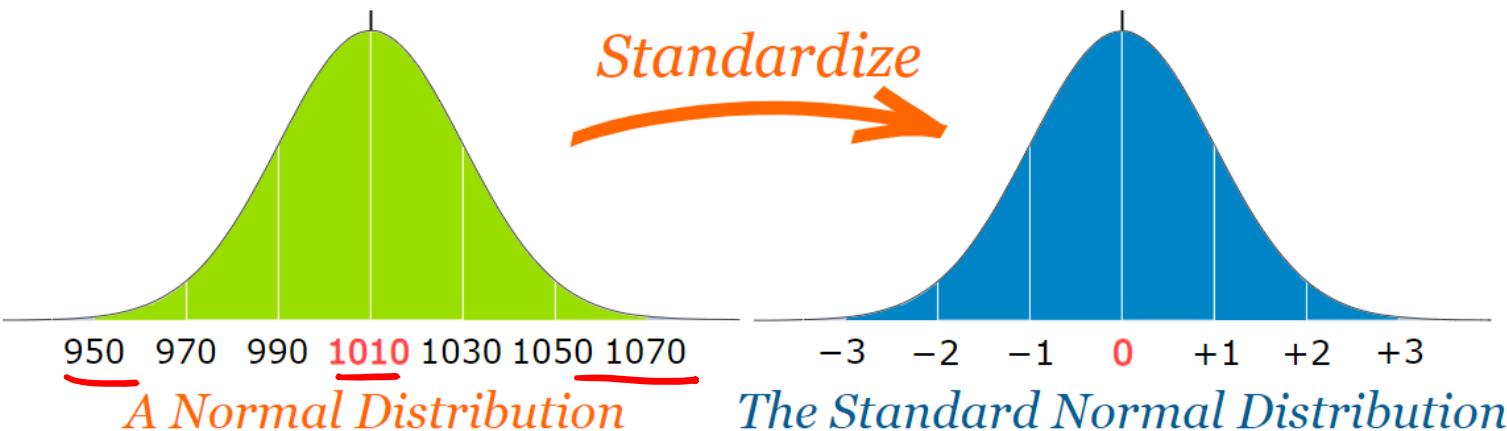

95% of values are within
2 standard deviations of the mean

99.7% of values are within
3 standard deviations of the mean

- So to convert a value to a Standard Score ("z-score"):
 - first subtract the mean,
 - then divide by the Standard Deviation
- And doing that is called "Standardizing":

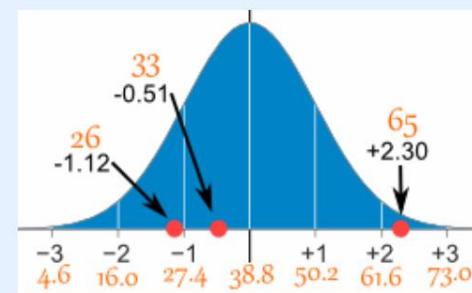

- We can take any Normal Distribution and convert it to The Standard Normal Distribution.
- **Example:** Travel Time
- A survey of daily travel time had these results (in minutes):
 - 26, 33, 65, 28, 34, 55, 25, 44, 50, 36, 26, 37, 43, 62, 35, 38, 45, 32, 28, 34
- The **Mean is 38.8 minutes**, and the **Standard Deviation is 11.4 minutes**
- Convert the values to z-scores ("standard scores").
- To convert **26**:
- first subtract the mean: $26 - 38.8 = -12.8$,
- then divide by the Standard Deviation: $-12.8/11.4 = -1.12$
- So **26 is -1.12 Standard Deviations from the Mean**

- Here are the first three conversions

Original Value	Calculation	Standard Score (z-score)
<u>26</u>	$(26-38.8) / 11.4 =$	<u>-1.12</u>
<u>33</u>	$(33-38.8) / 11.4 =$	<u>-0.51</u>
<u>65</u>	$(65-38.8) / 11.4 =$	<u>+2.30</u>
...

And here they are graphically:

$$z = \frac{x - \mu}{\sigma}$$

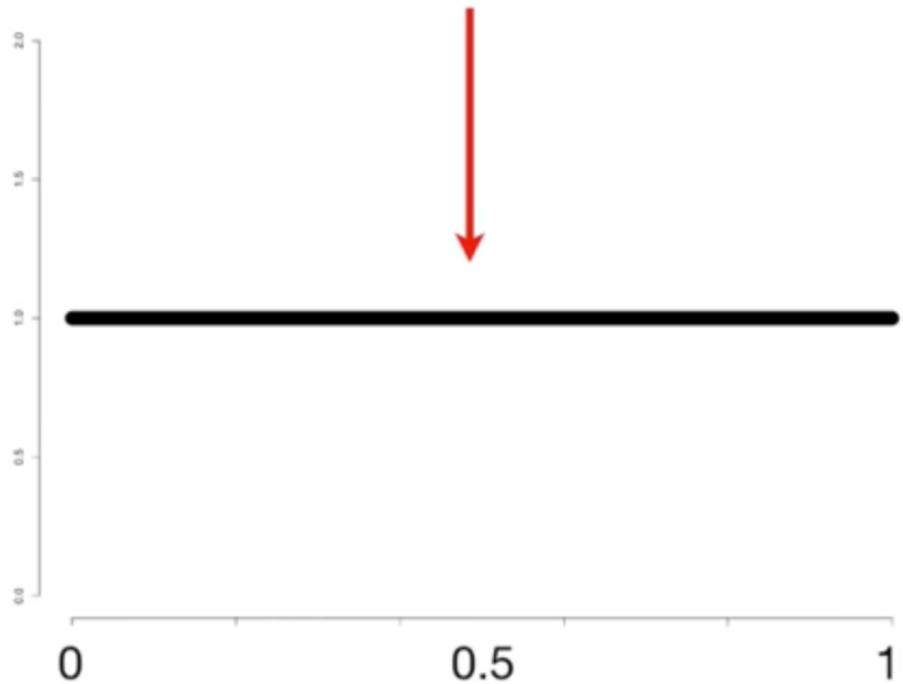

- **z** is the "z-score" (Standard Score)
- **x** is the value to be standardized
- **μ** ('mu") is the mean
- **σ** ("sigma") is the standard deviation

The Central Limit Theorem is the basis for
a lot of statistics and the good news is that it
is a pretty simple concept.

Like most things in statistics, I think The
Central Limit Theorem is easiest to
understand if we look at some examples.

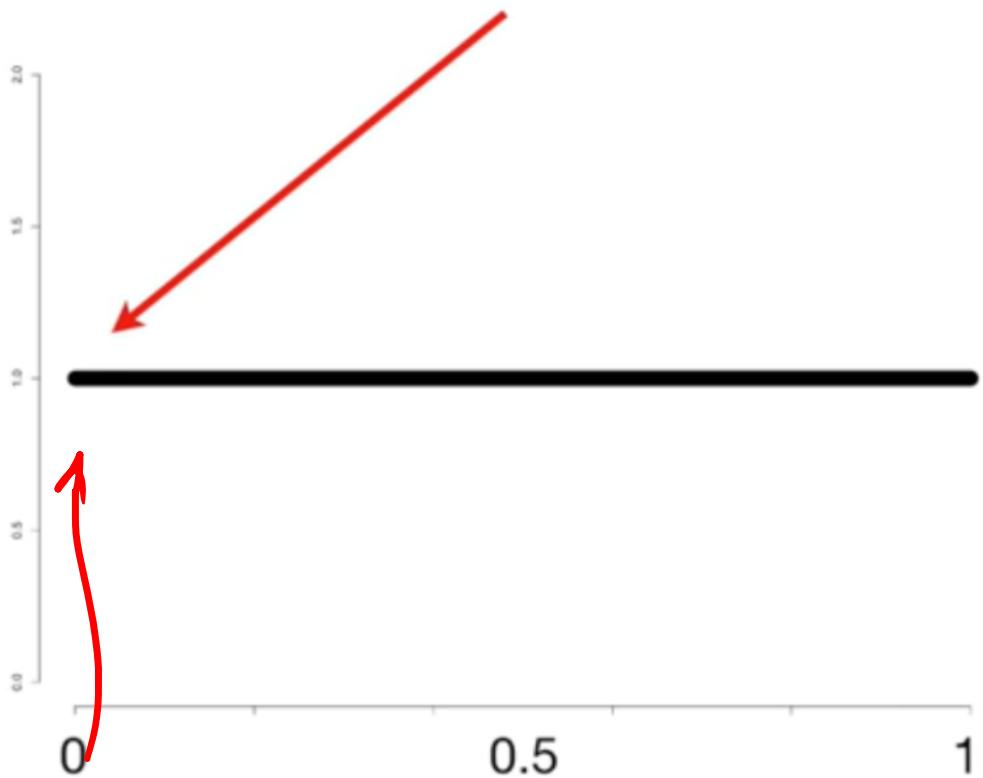

Central Limit Theorem

So let's start with a Uniform Distribution.

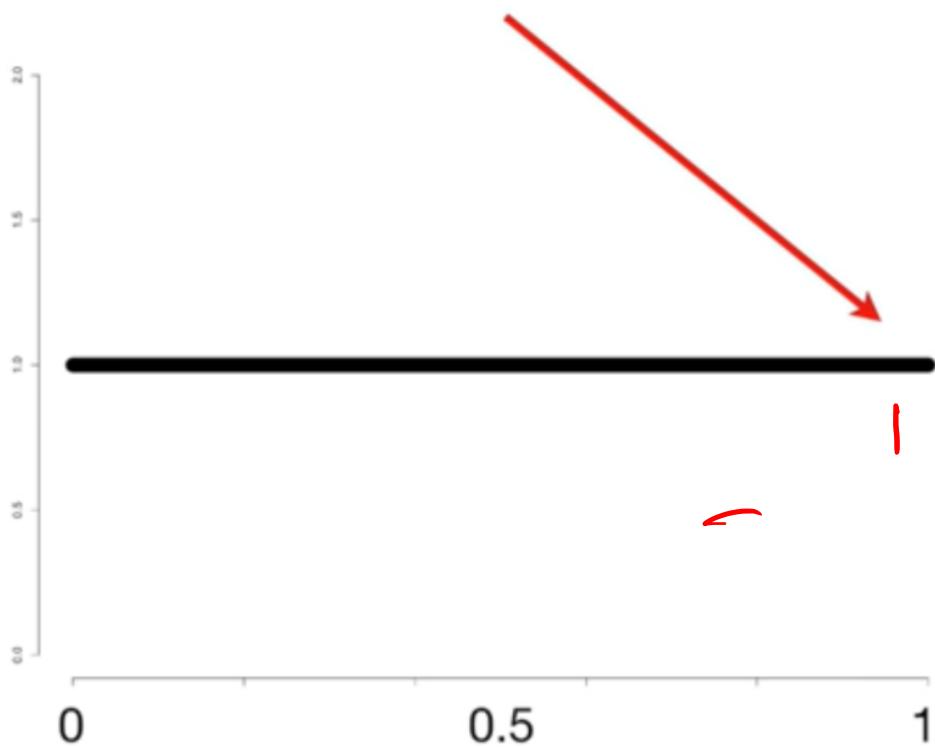

Central Limit Theorem

This one goes from 0...

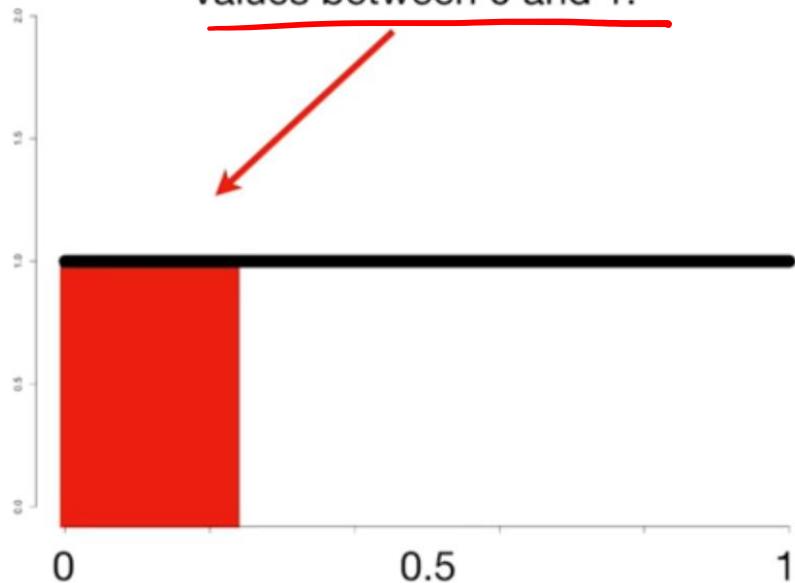

Central Limit Theorem

...to 1.

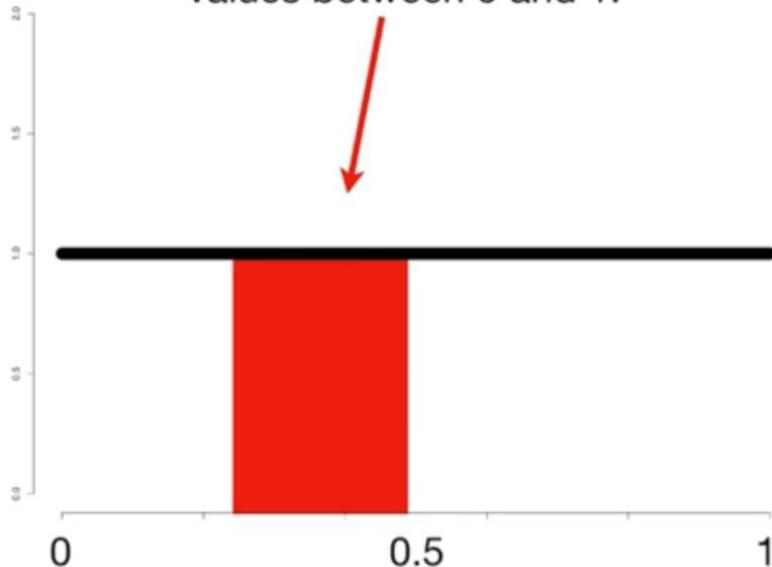

Central Limit Theorem

It's called the uniform distribution because there is an equal probability of selecting values between 0 and 1.

Central Limit Theorem

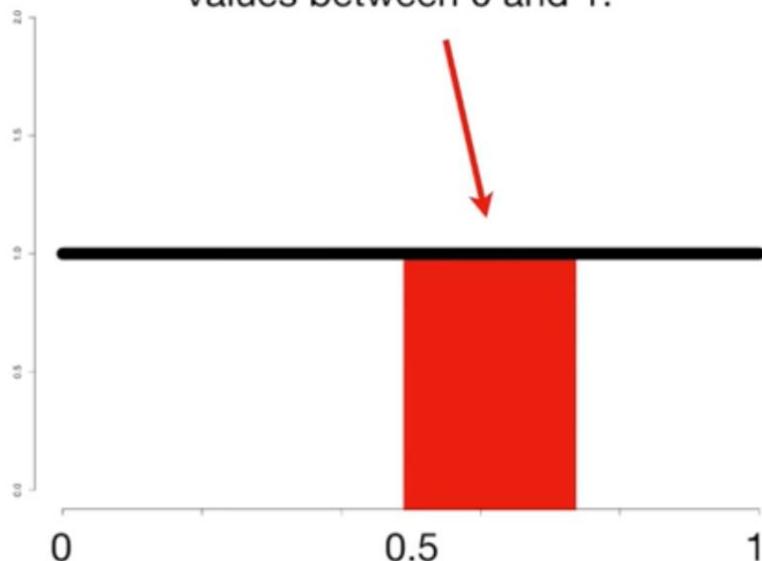

It's called the uniform distribution because there is an equal probability of selecting values between 0 and 1.

Central Limit Theorem

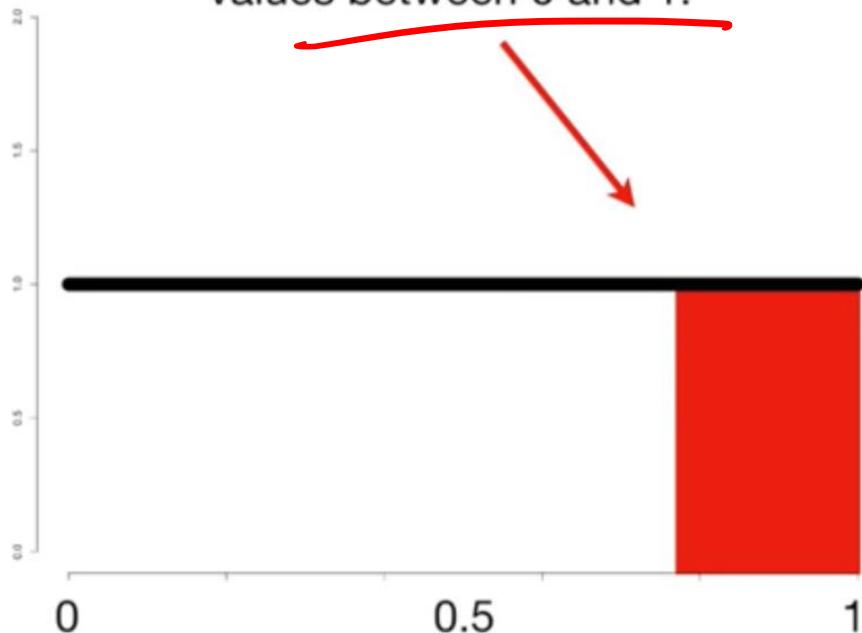

upGrad

It's called the uniform distribution because there is an equal probability of selecting values between 0 and 1.

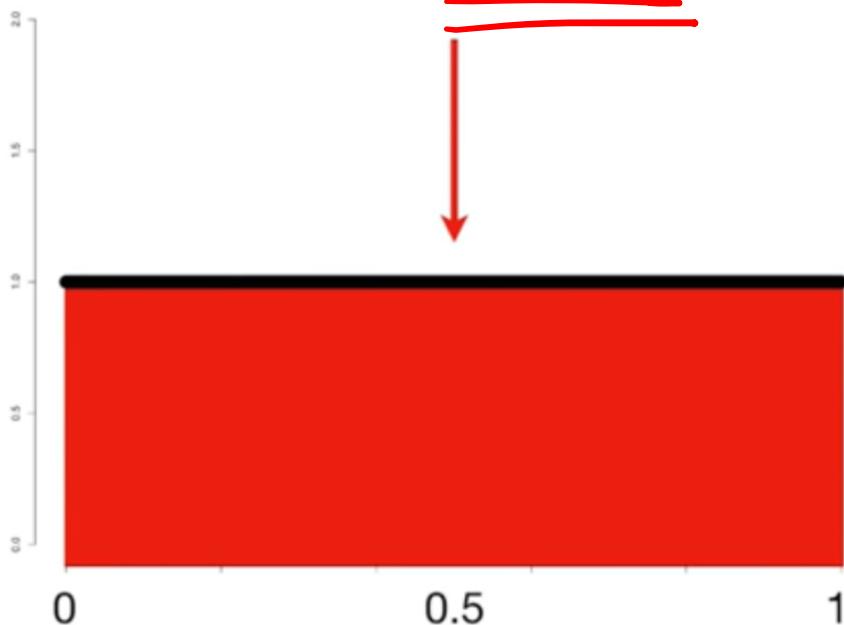

Central Limit Theorem

It's called the uniform distribution because there is an equal probability of selecting values between 0 and 1.

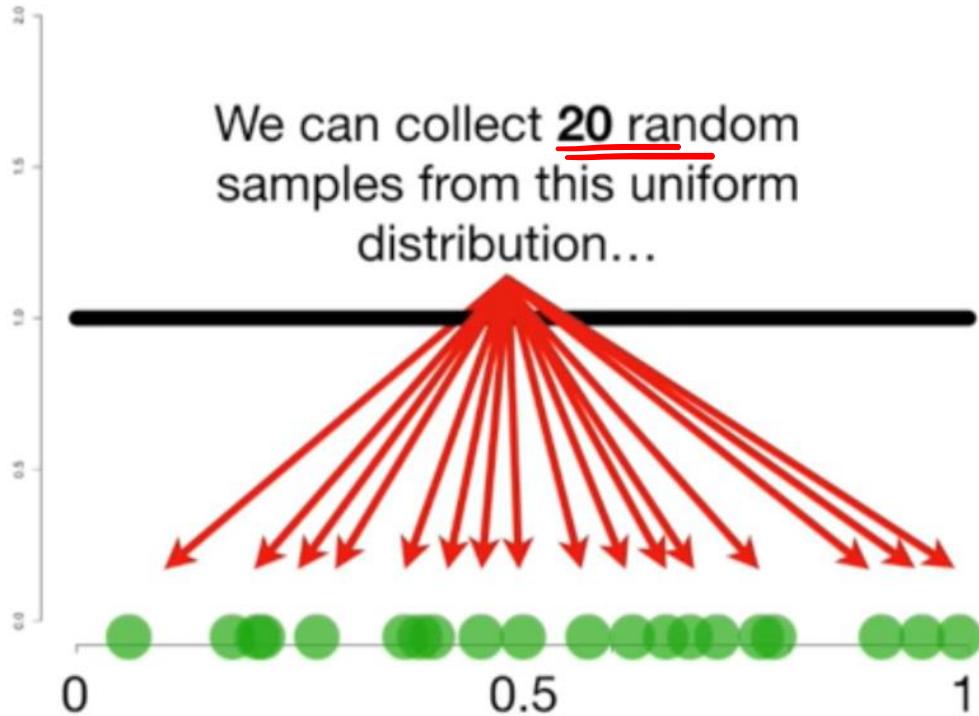

Central Limit Theorem

The probabilities are all equal,
and thus, are “uniform”.

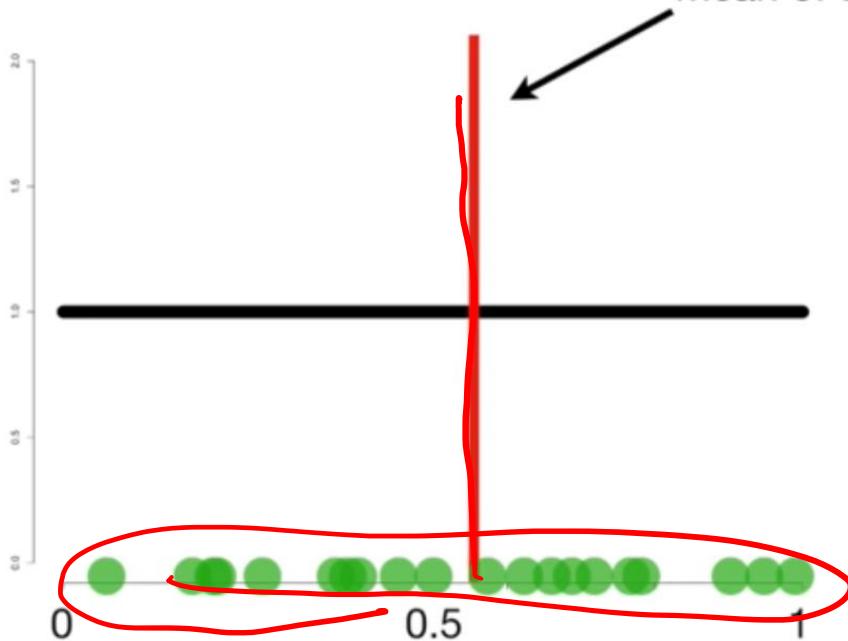

Central Limit Theorem

We can collect 20 random samples from this uniform distribution...

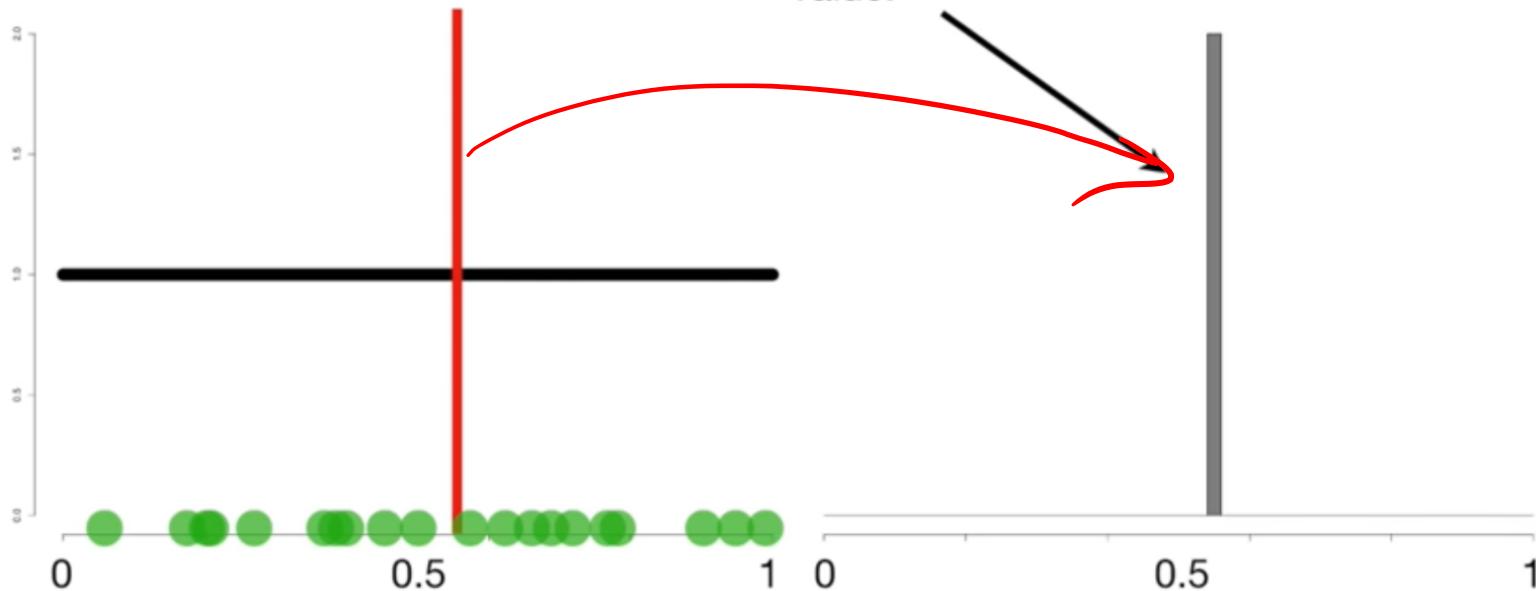

Central Limit Theorem

...and then calculate the mean of the samples.

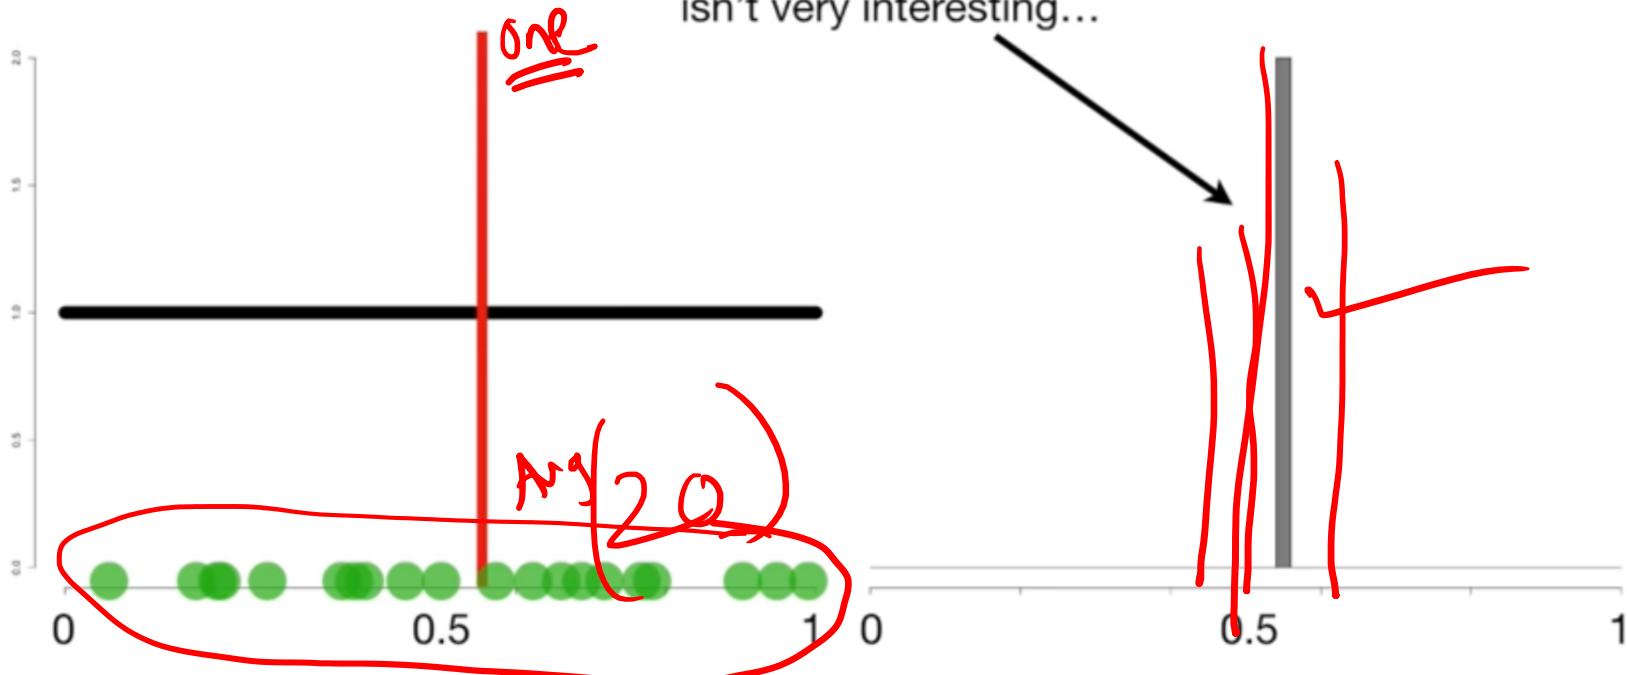

Central Limit Theorem

On the right, we can draw a histogram of the mean value.

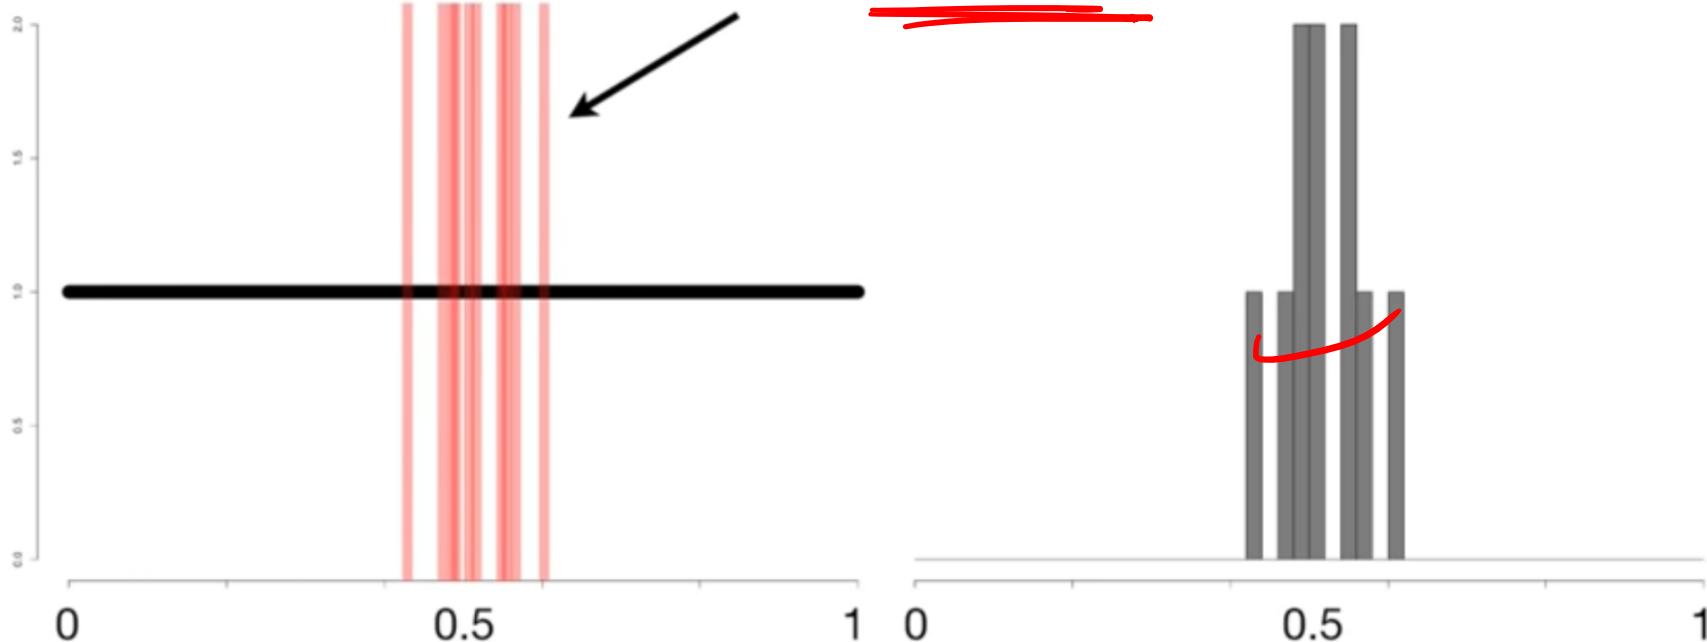

Central Limit Theorem

Since we only have one
mean value, the histogram
isn't very interesting...

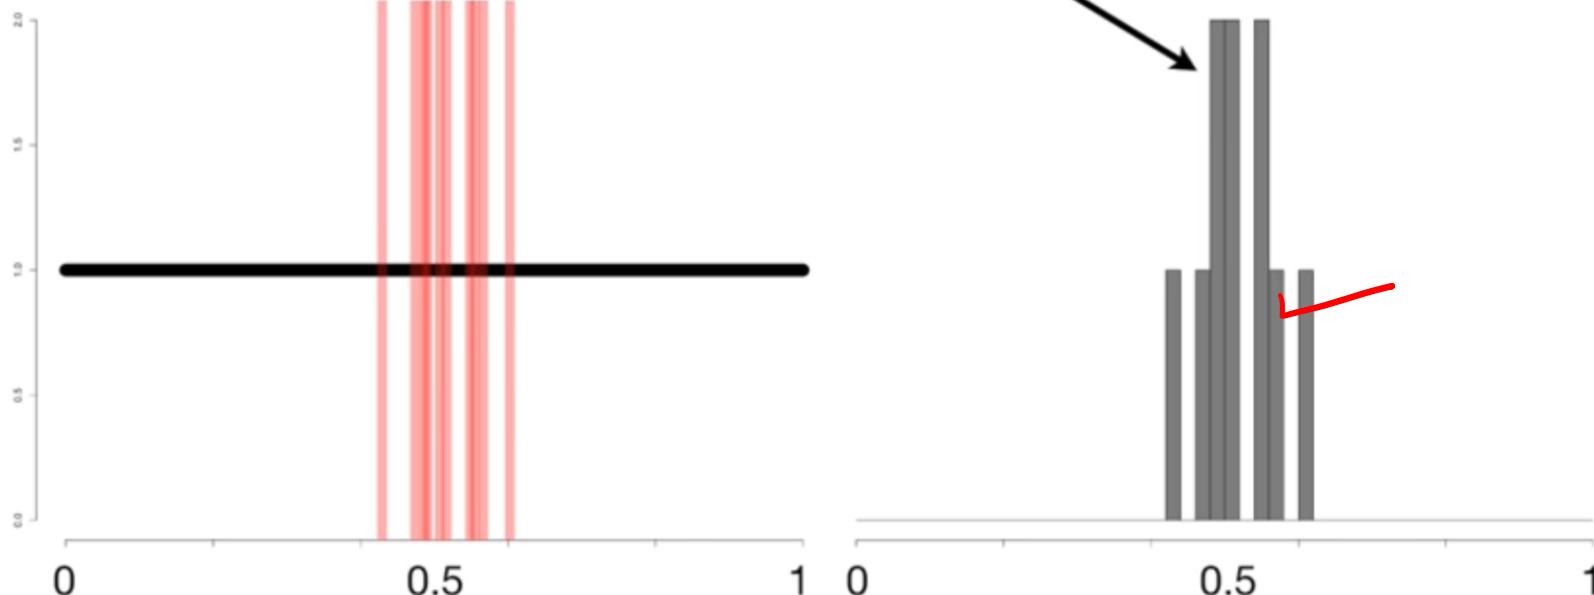

Central Limit Theorem

...but after we collect 10
more samples and
calculate 10 more means...

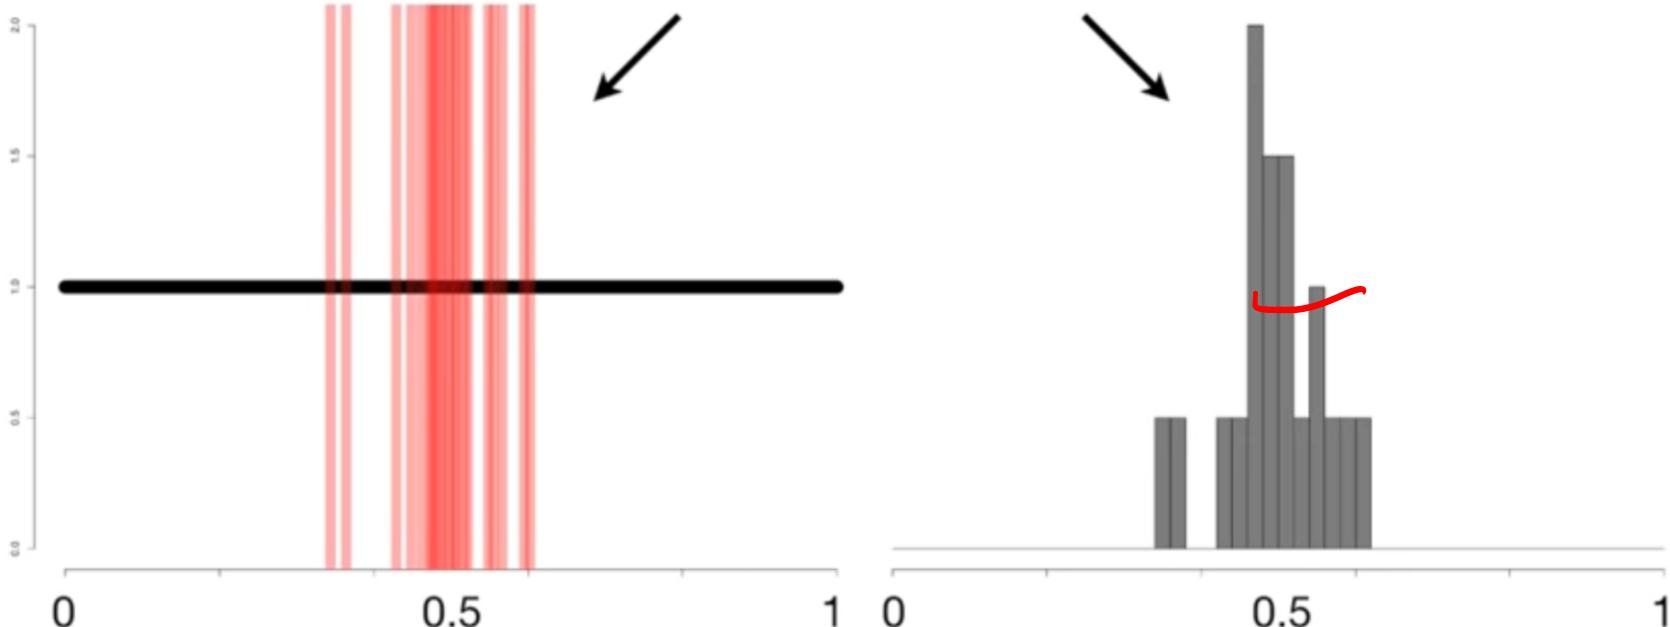

Central Limit Theorem

...the histogram starts to look at little more interesting.

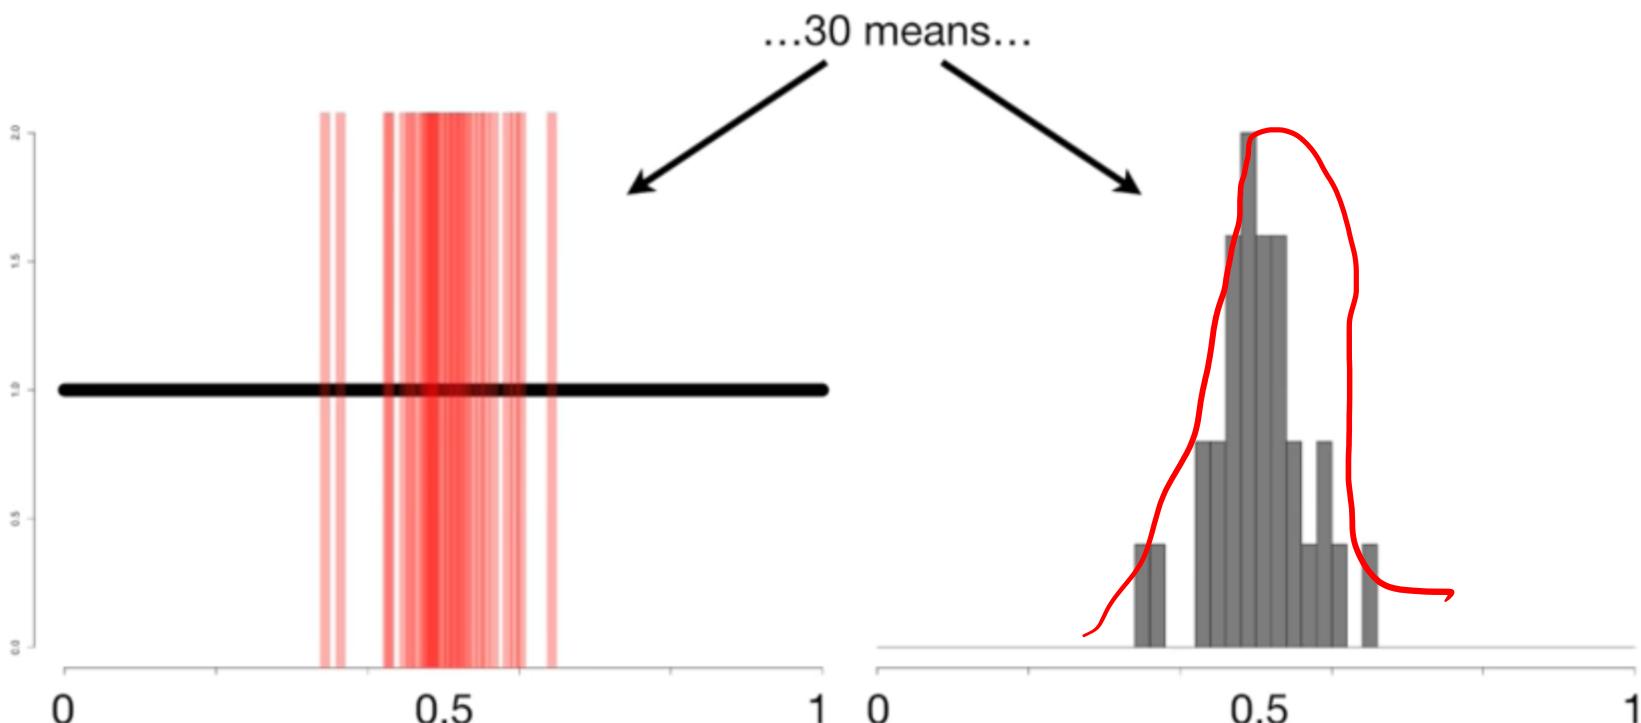

Central Limit Theorem

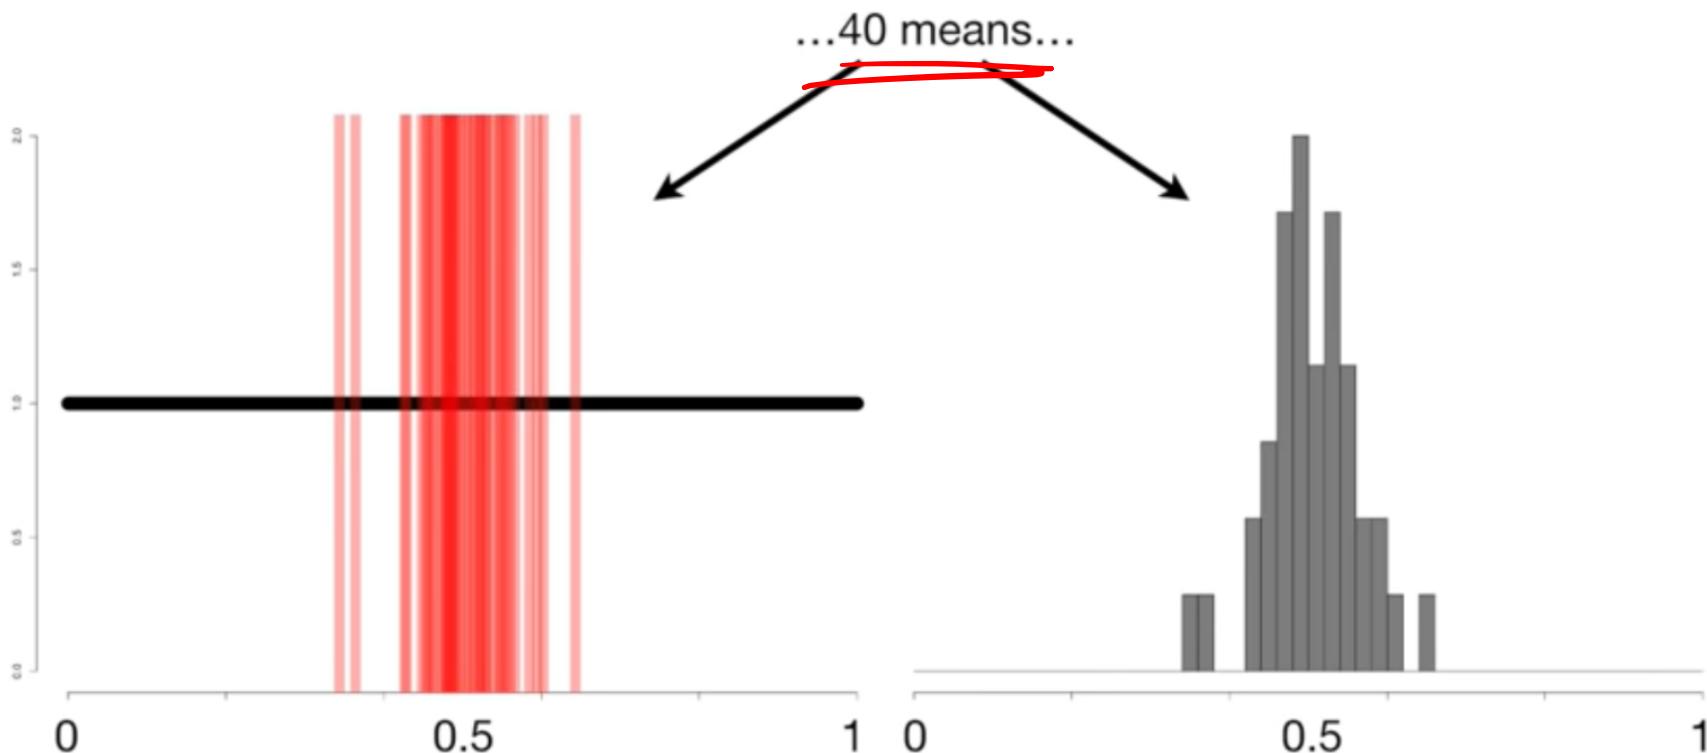

Here's the histogram after
collecting 20 samples and
calculating 20 means...

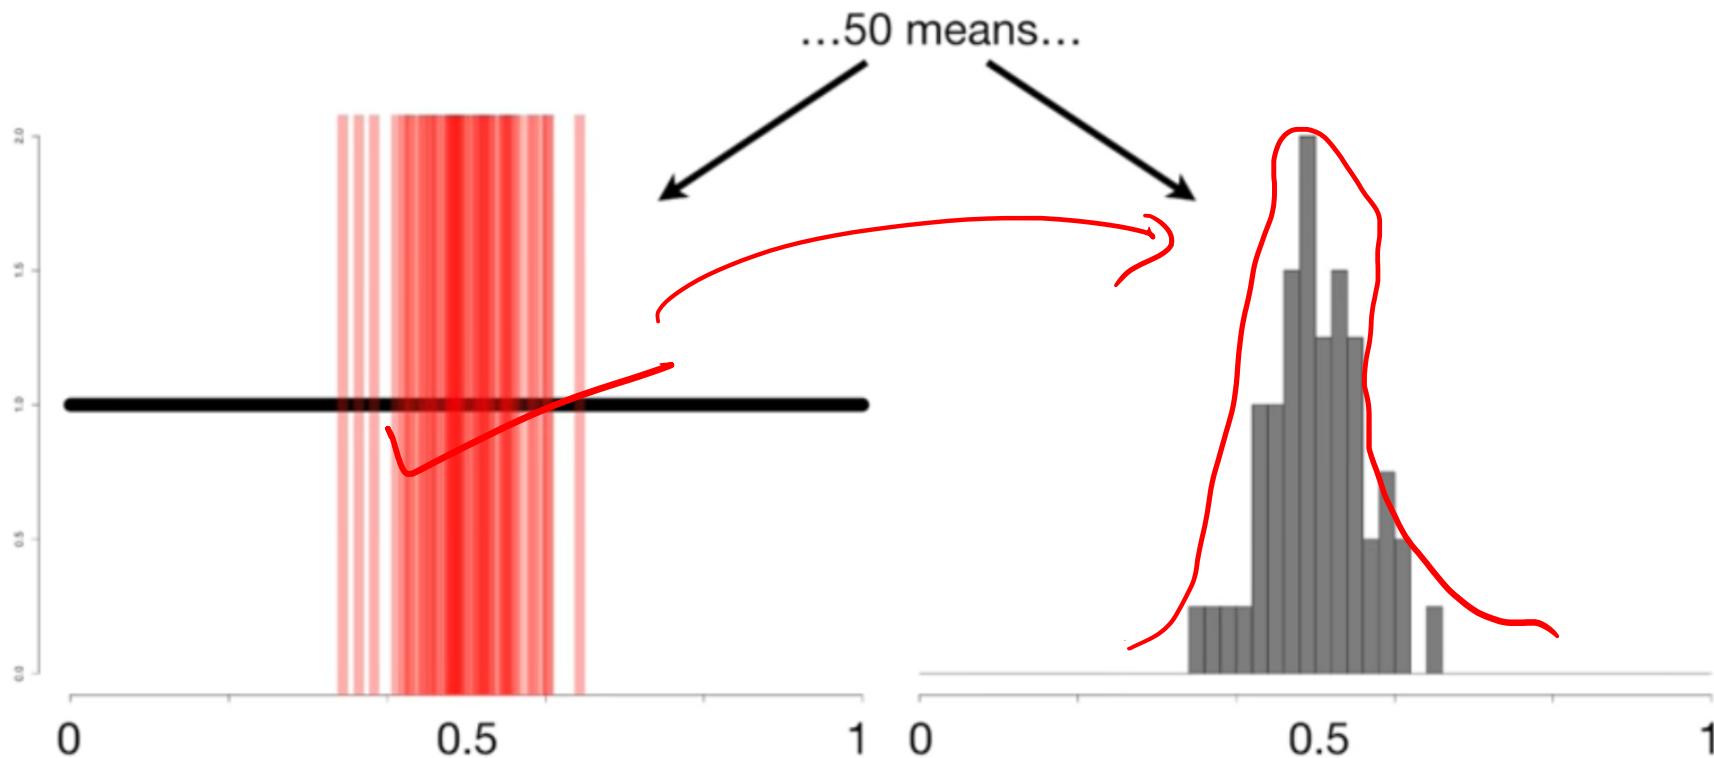

Central Limit Theorem

Central Limit Theorem

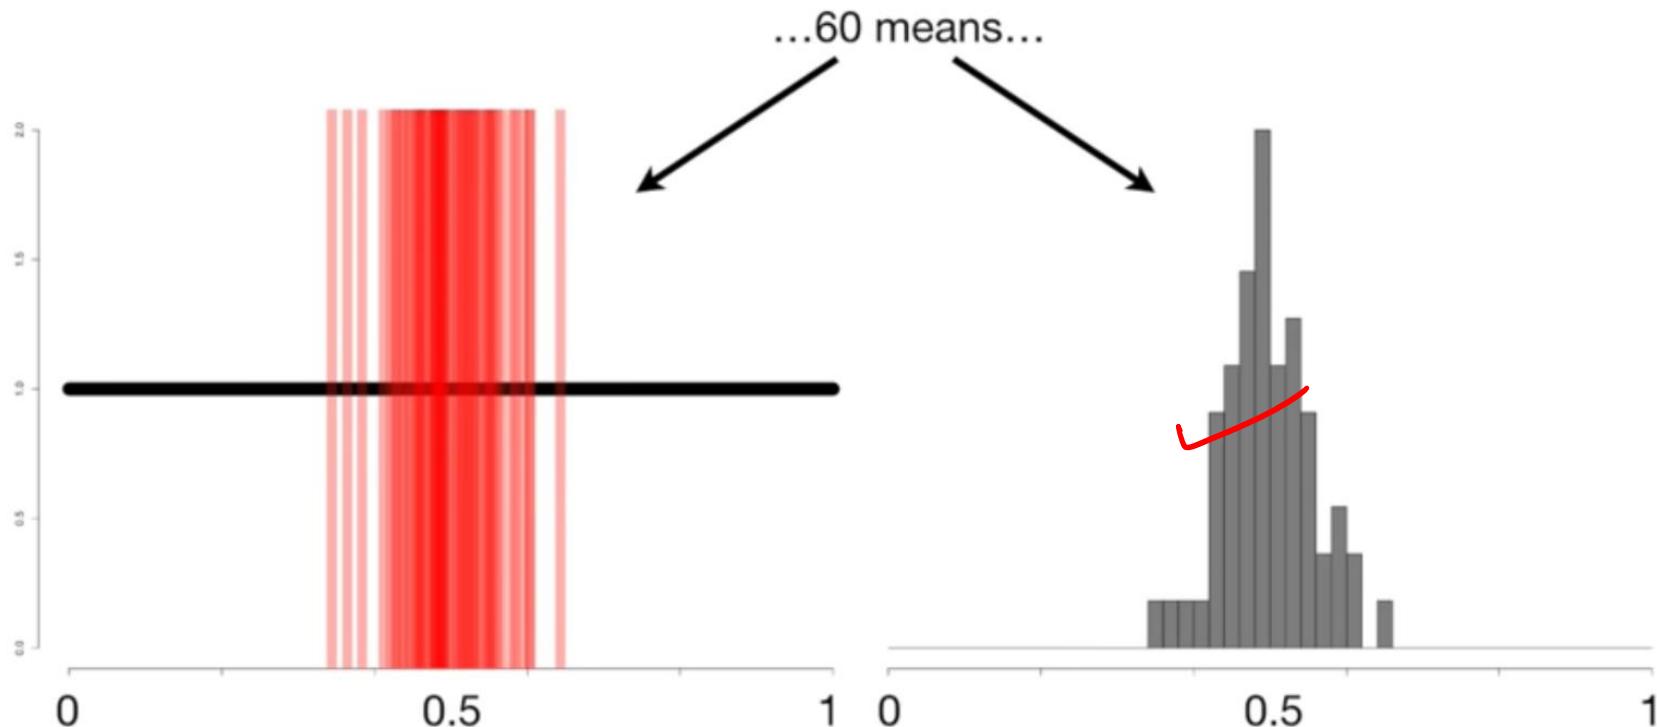

Central Limit Theorem

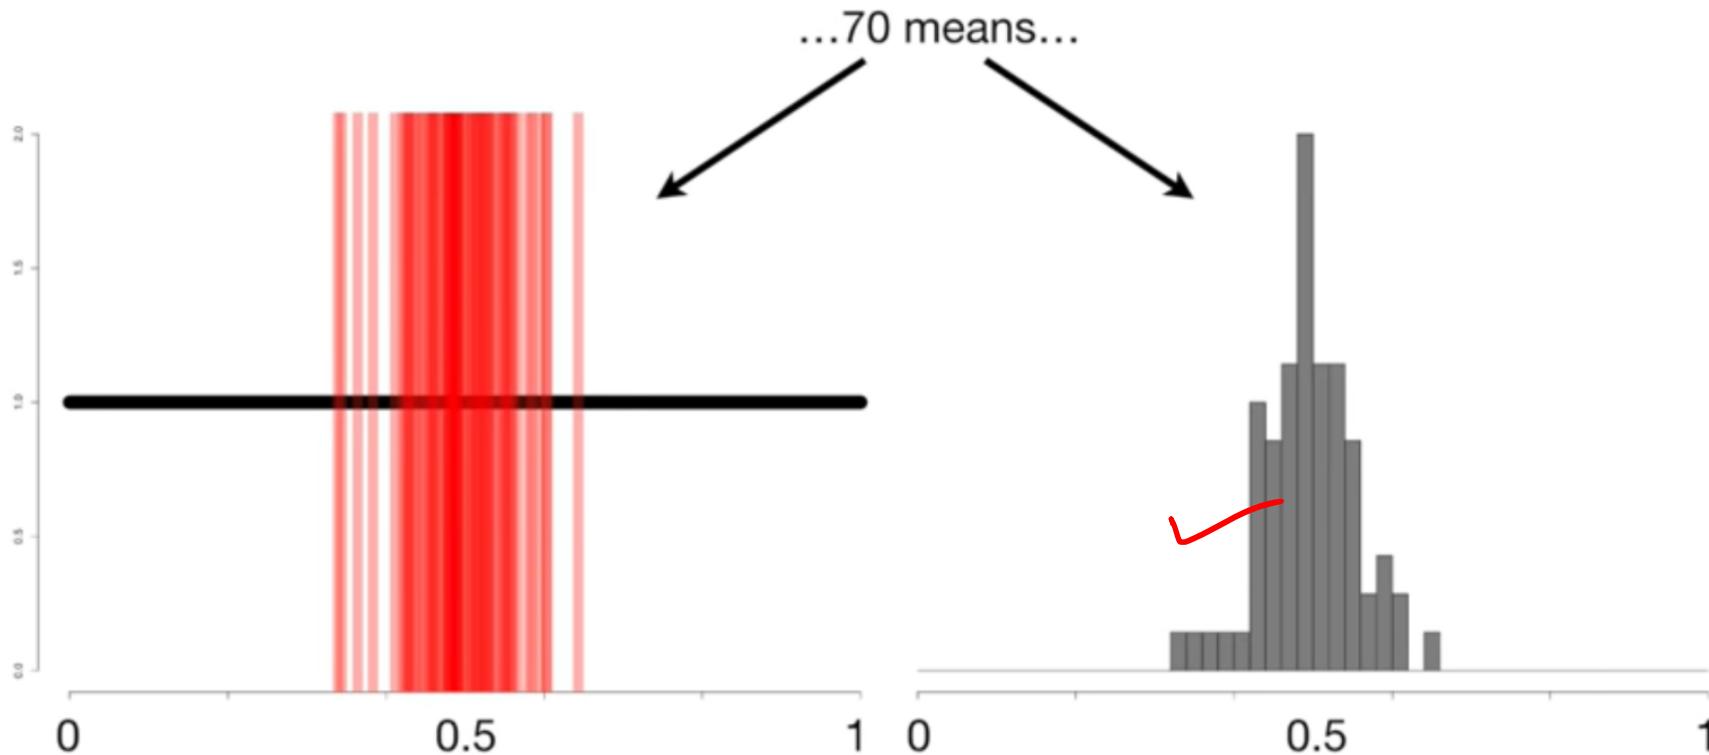

Central Limit Theorem

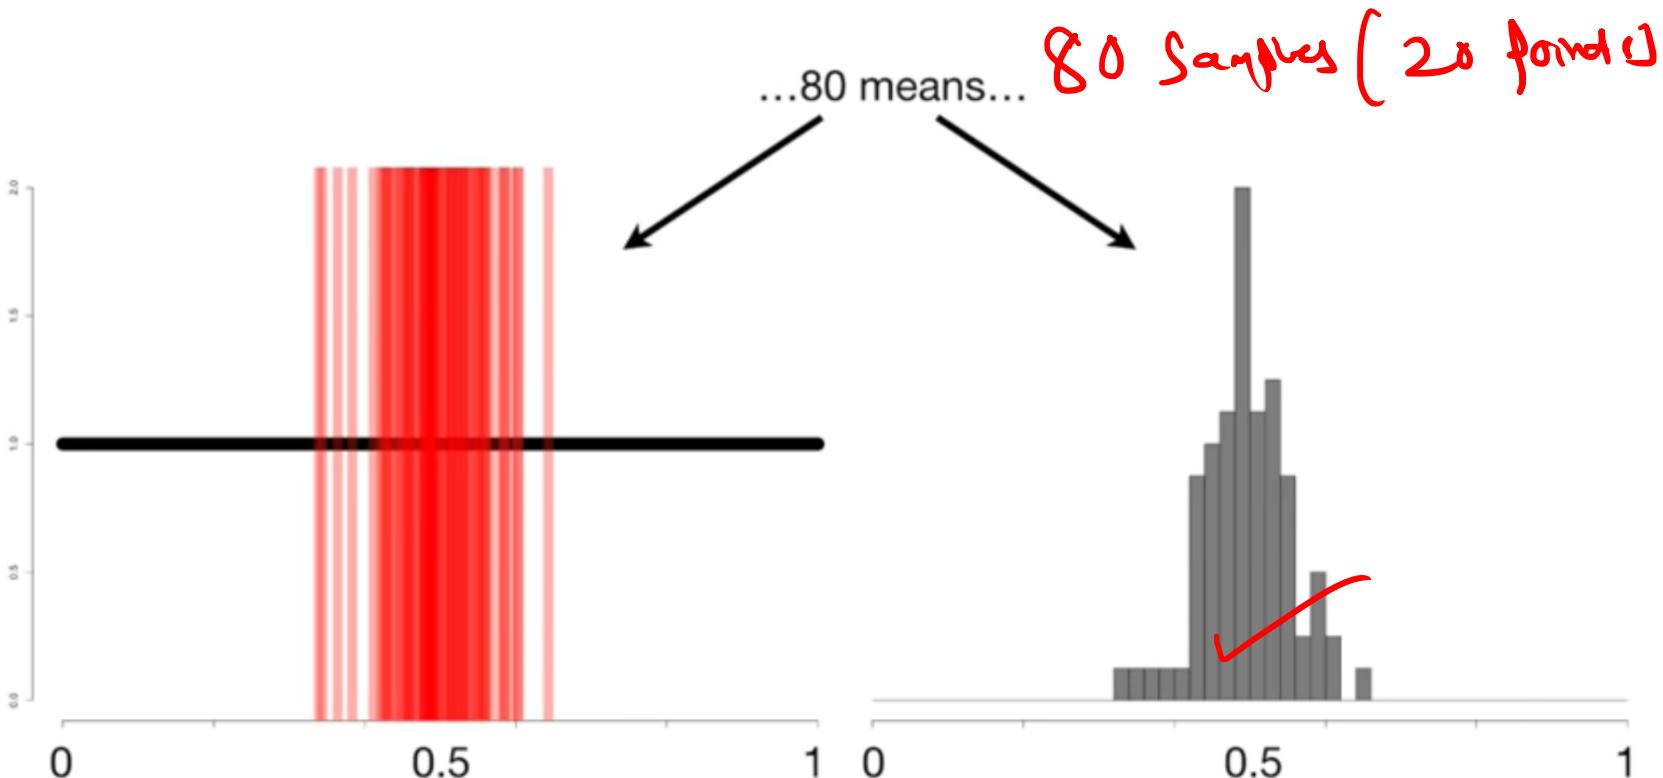

upGrad

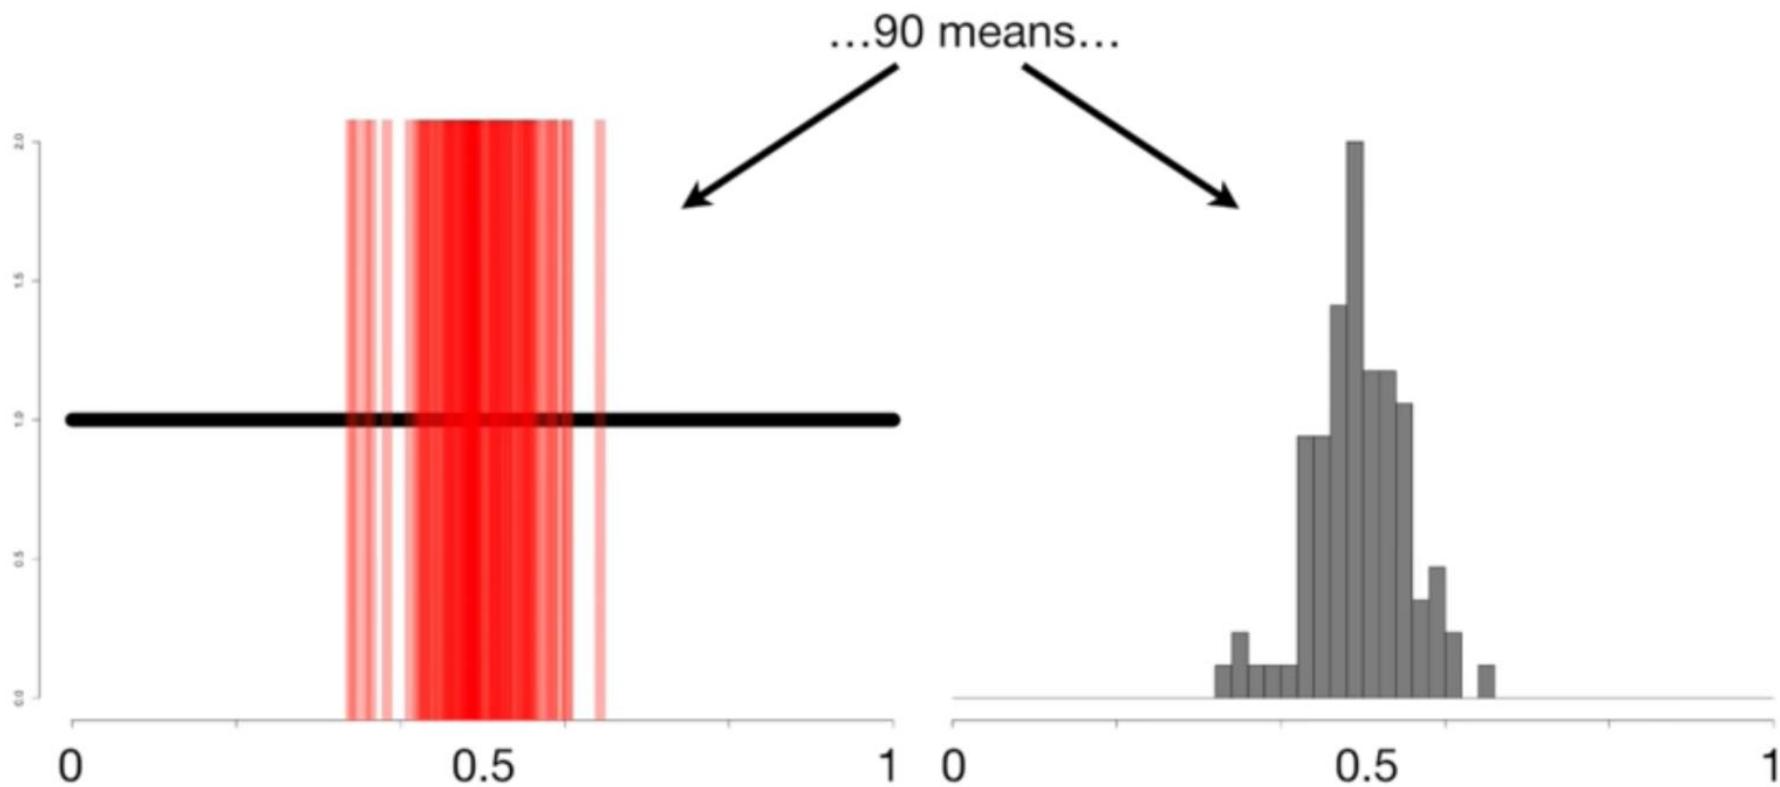

Central Limit Theorem

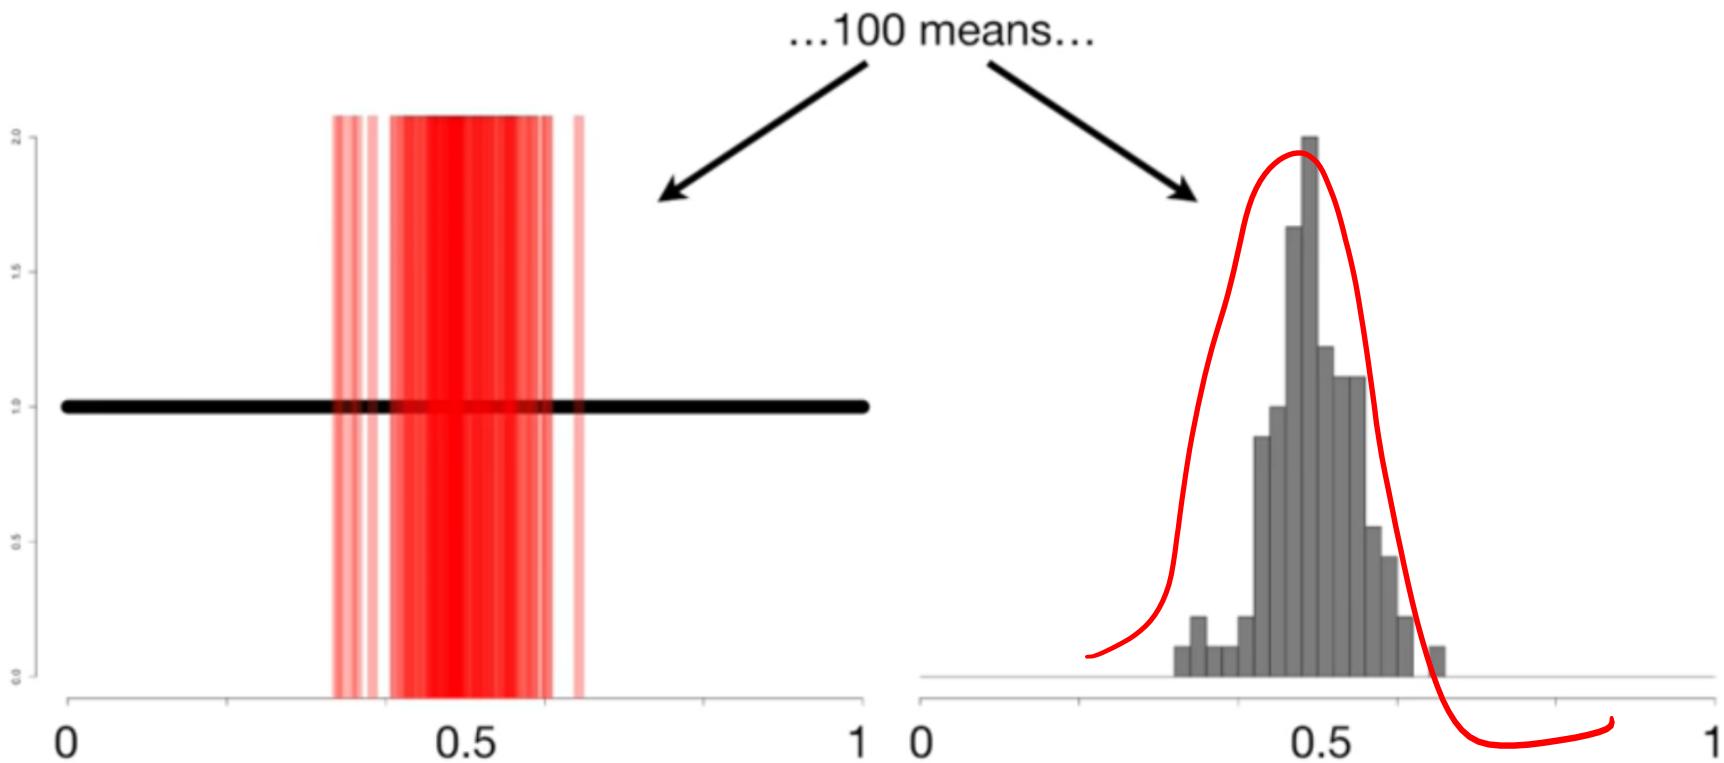

Central Limit Theorem

Central Limit Theorem

Central Limit Theorem

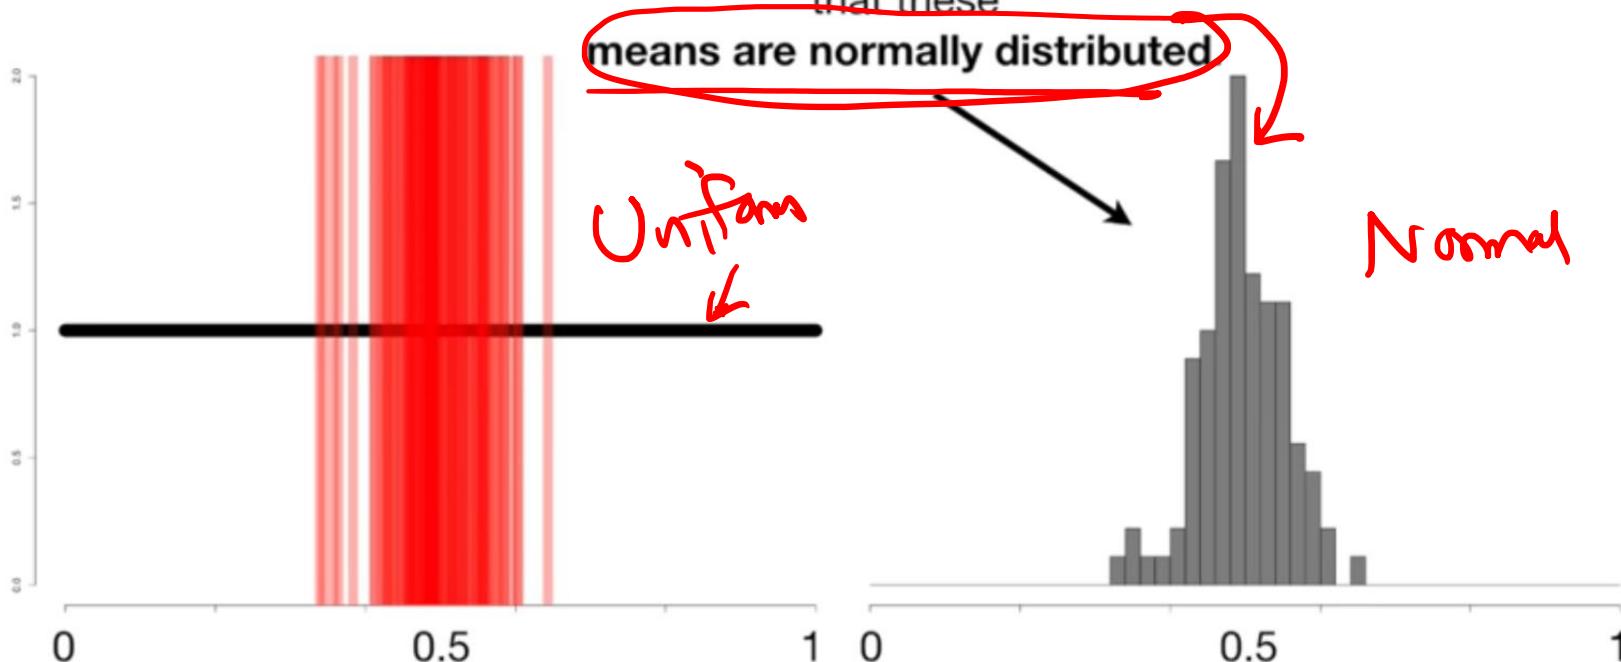

Central Limit Theorem

After adding 100 means to the histogram, it's pretty easy to see that these

means are normally distributed

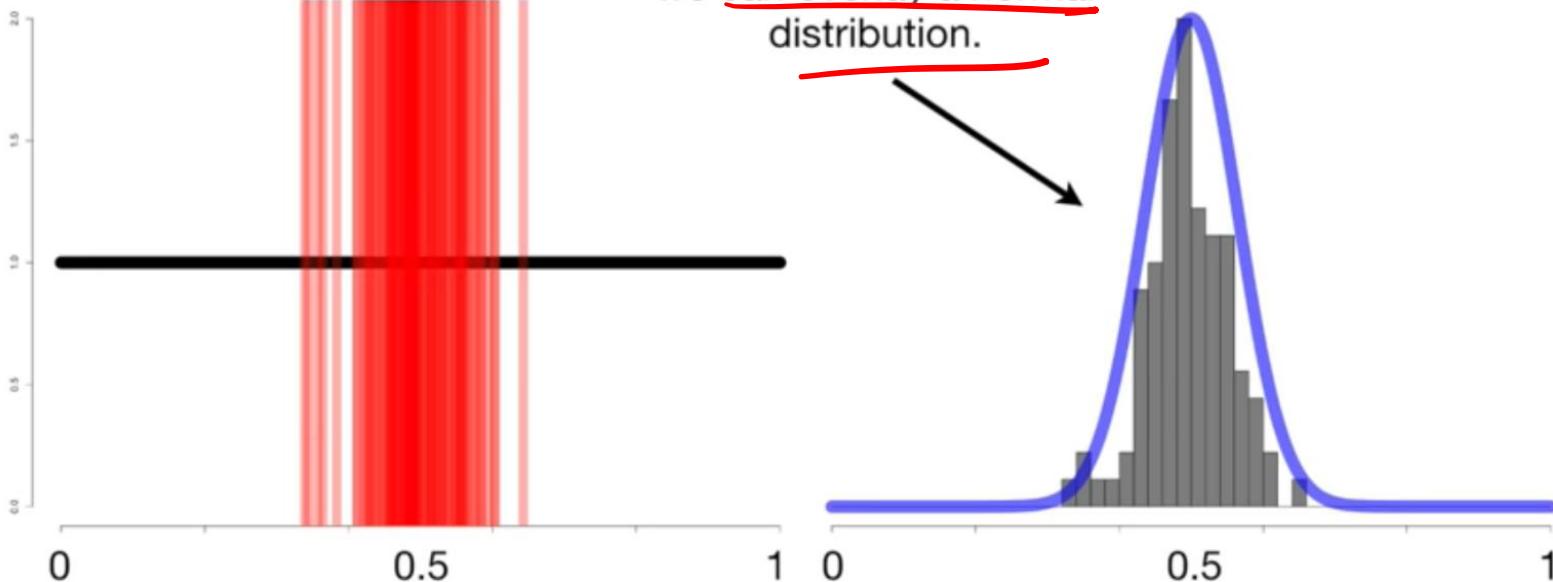

Uniform

Normal

Central Limit Theorem

However, to make super easy to see that the means are normally distributed, we can overlay a normal distribution.

Central Limit Theorem

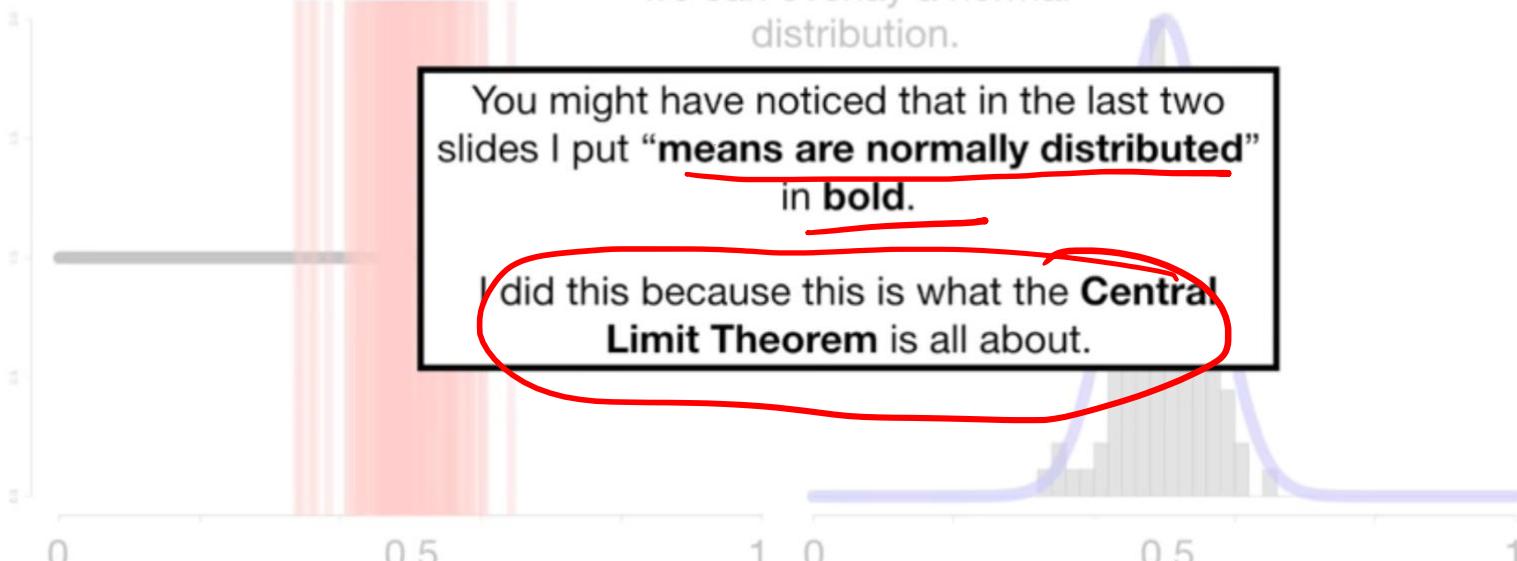

However, to make super easy to see that the

means are normally distributed,

we can overlay a normal distribution.

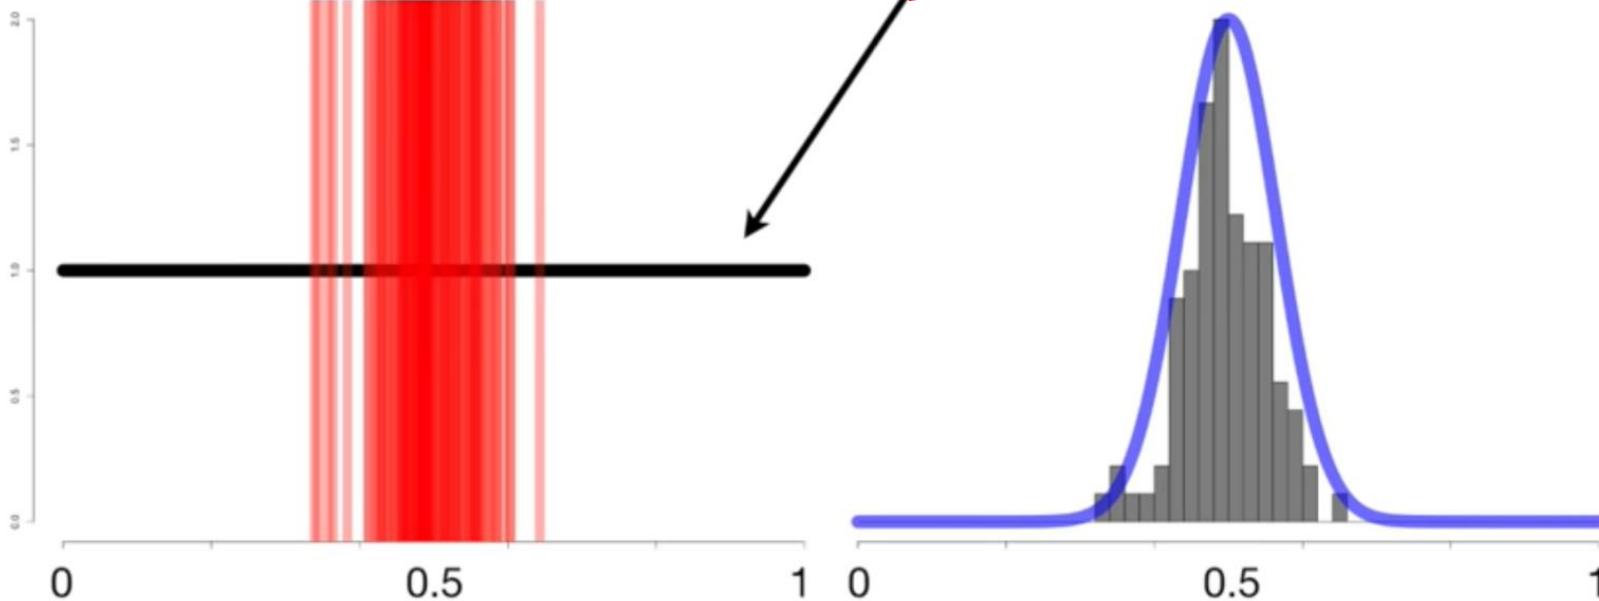

You might have noticed that in the last two slides I put "**means are normally distributed**" in **bold**.

I did this because this is what the **Central Limit Theorem** is all about.

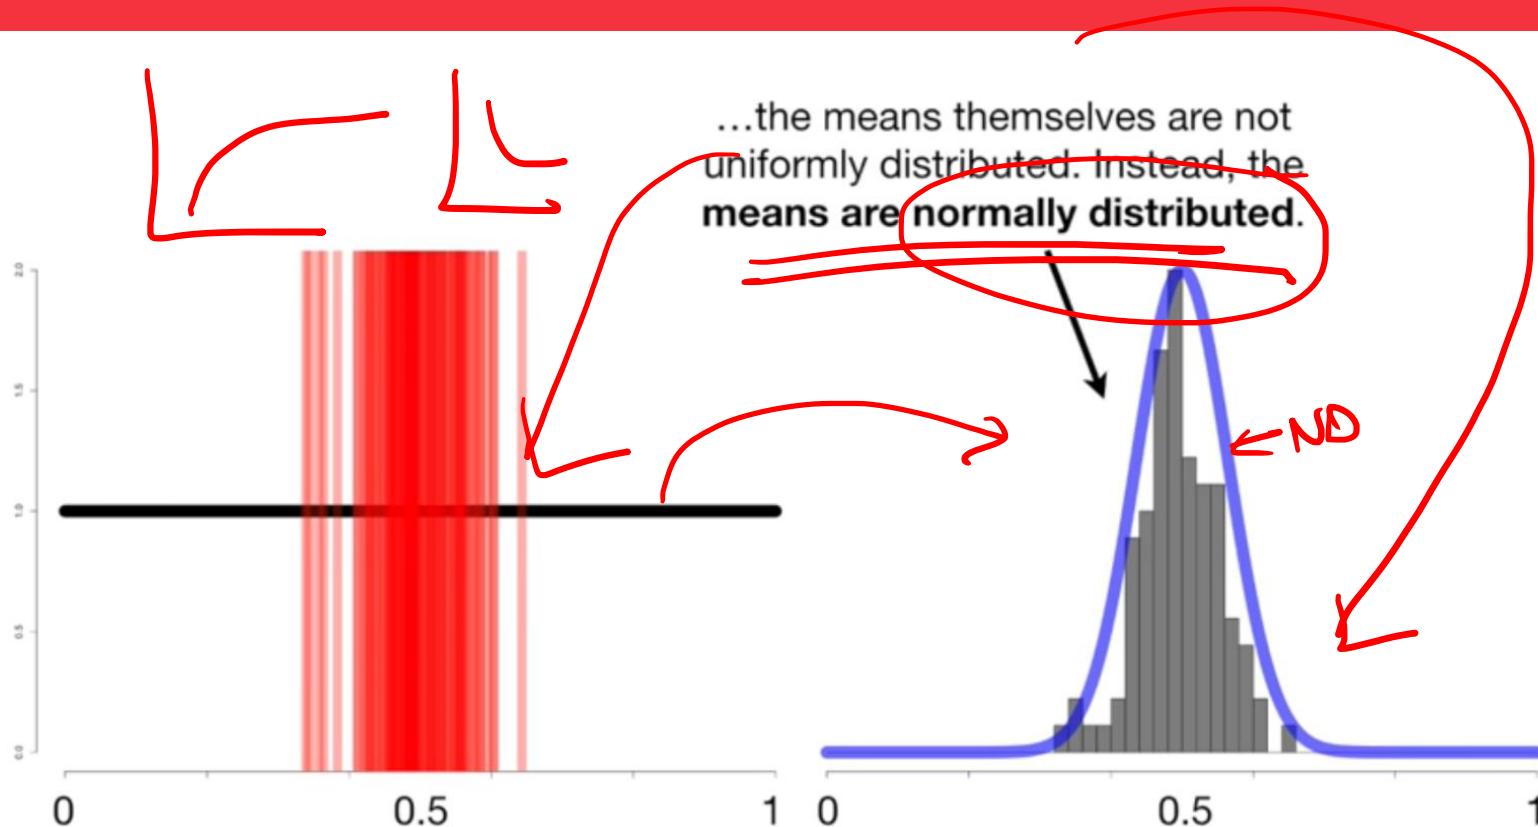

Central Limit Theorem

Even though these means
were calculated using data
from a uniform distribution...

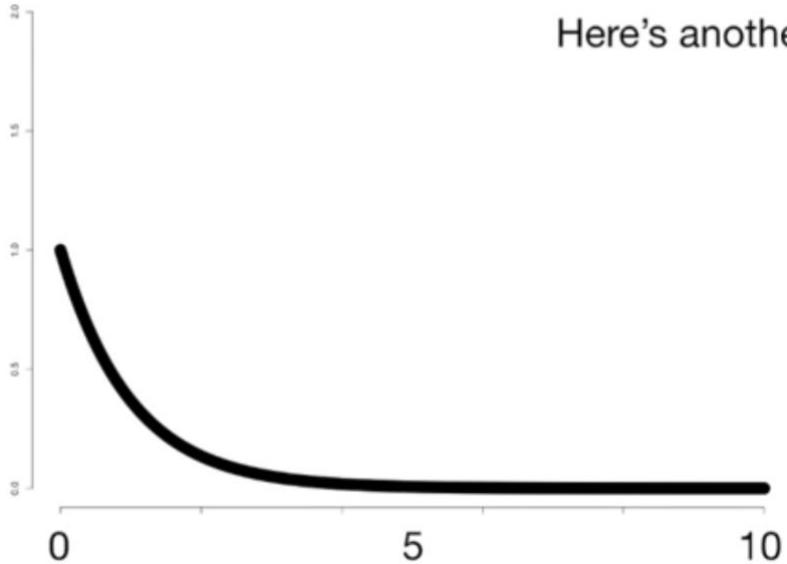

Central Limit Theorem

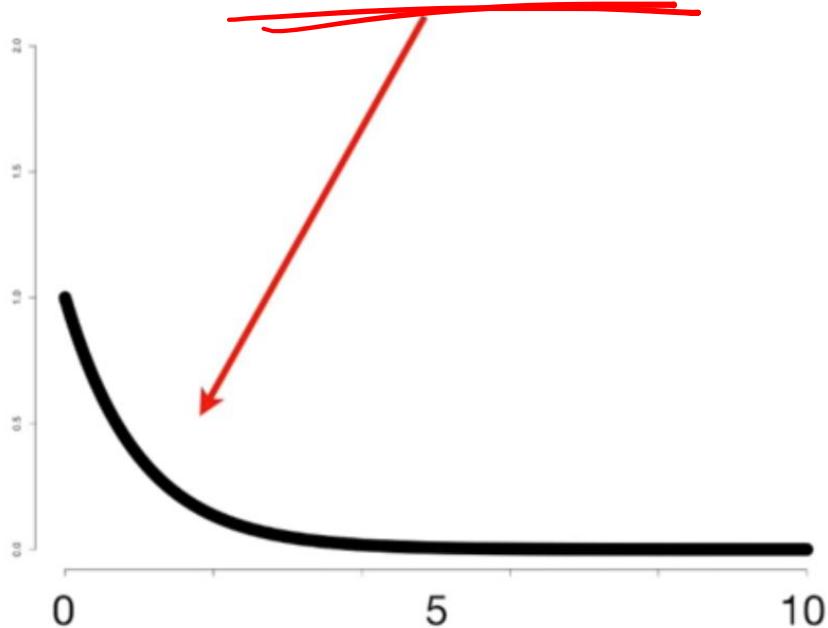

Central Limit Theorem

Here's another example...

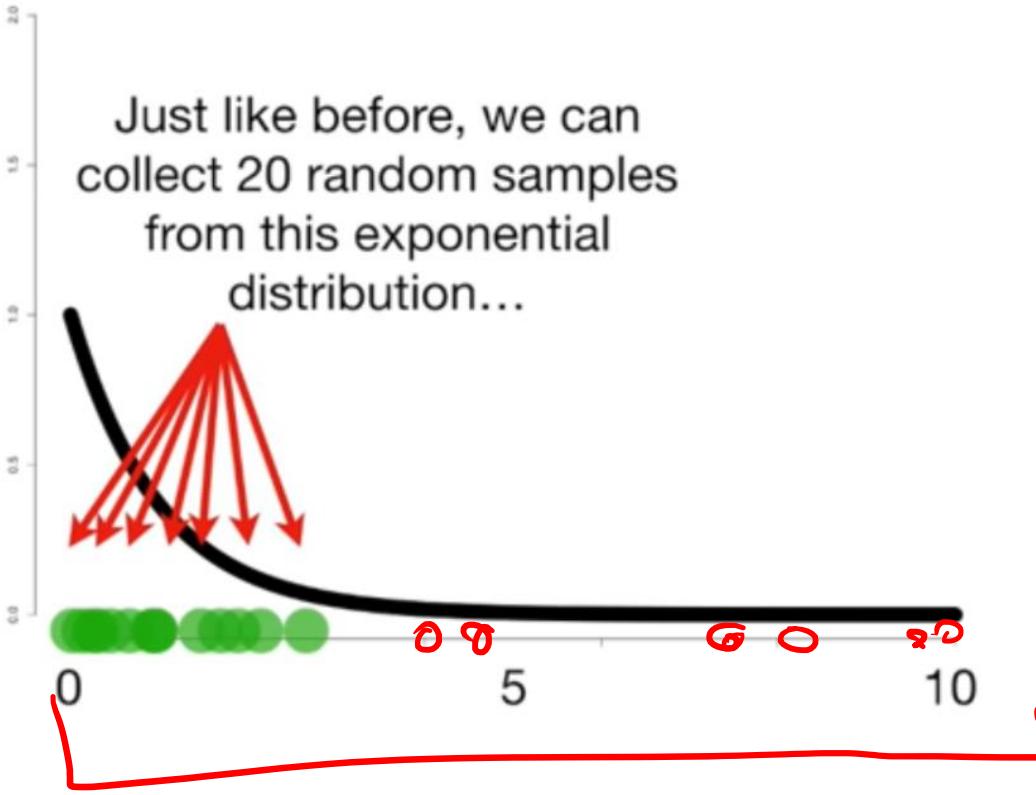

Central Limit Theorem

This time we'll start with an Exponential Distribution.

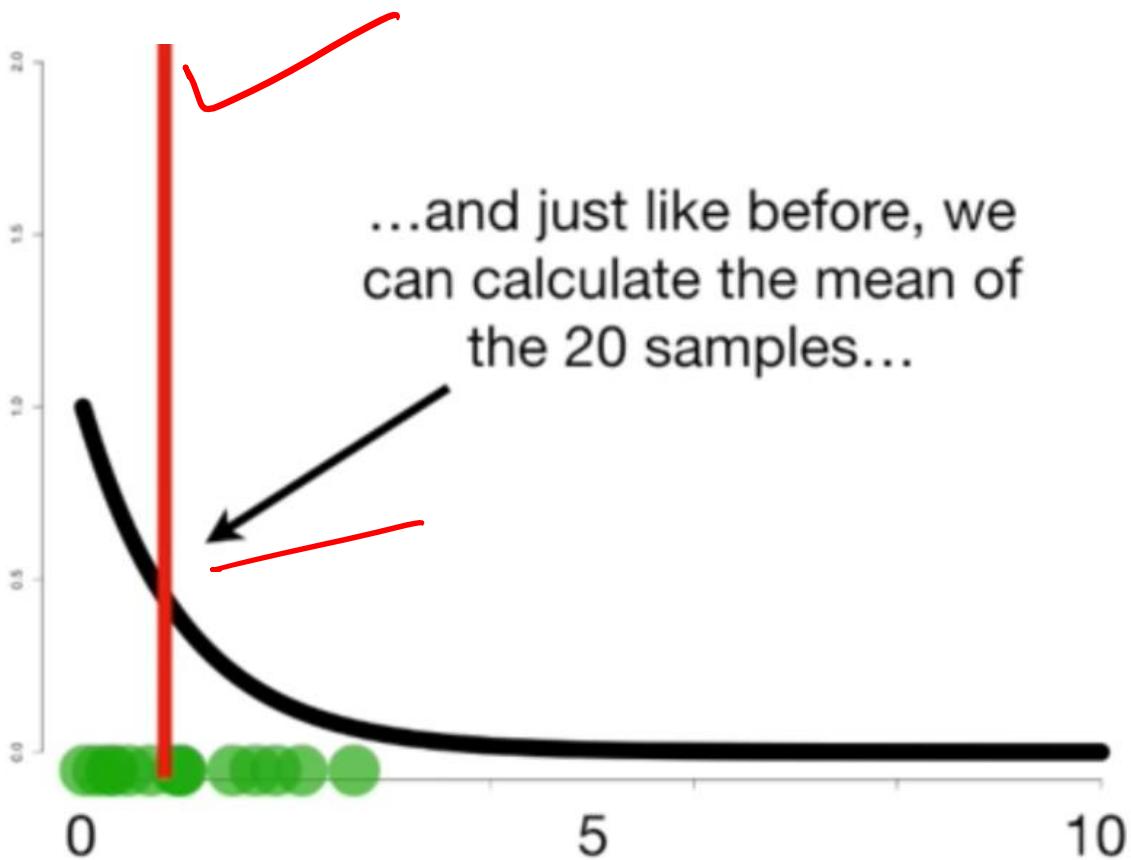

Central Limit Theorem

Just like before, we can collect 20 random samples from this exponential distribution...

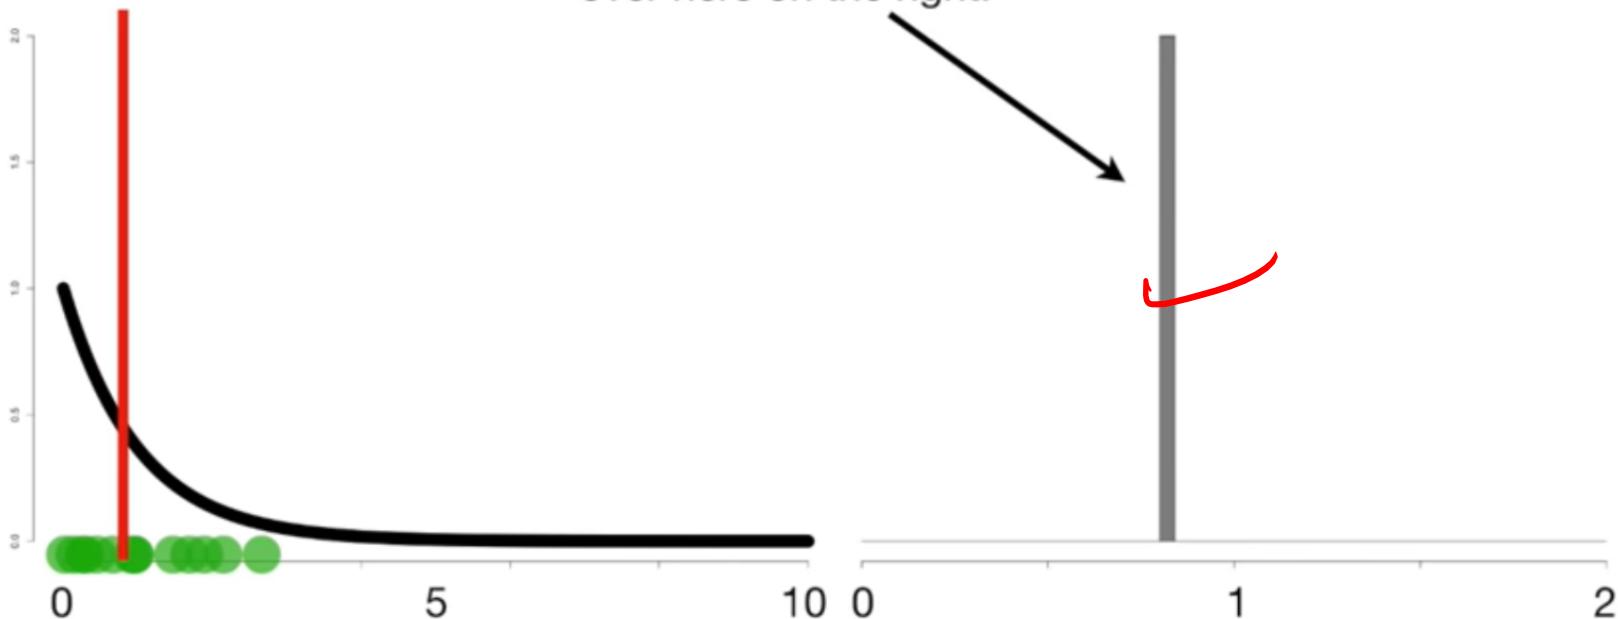

Central Limit Theorem

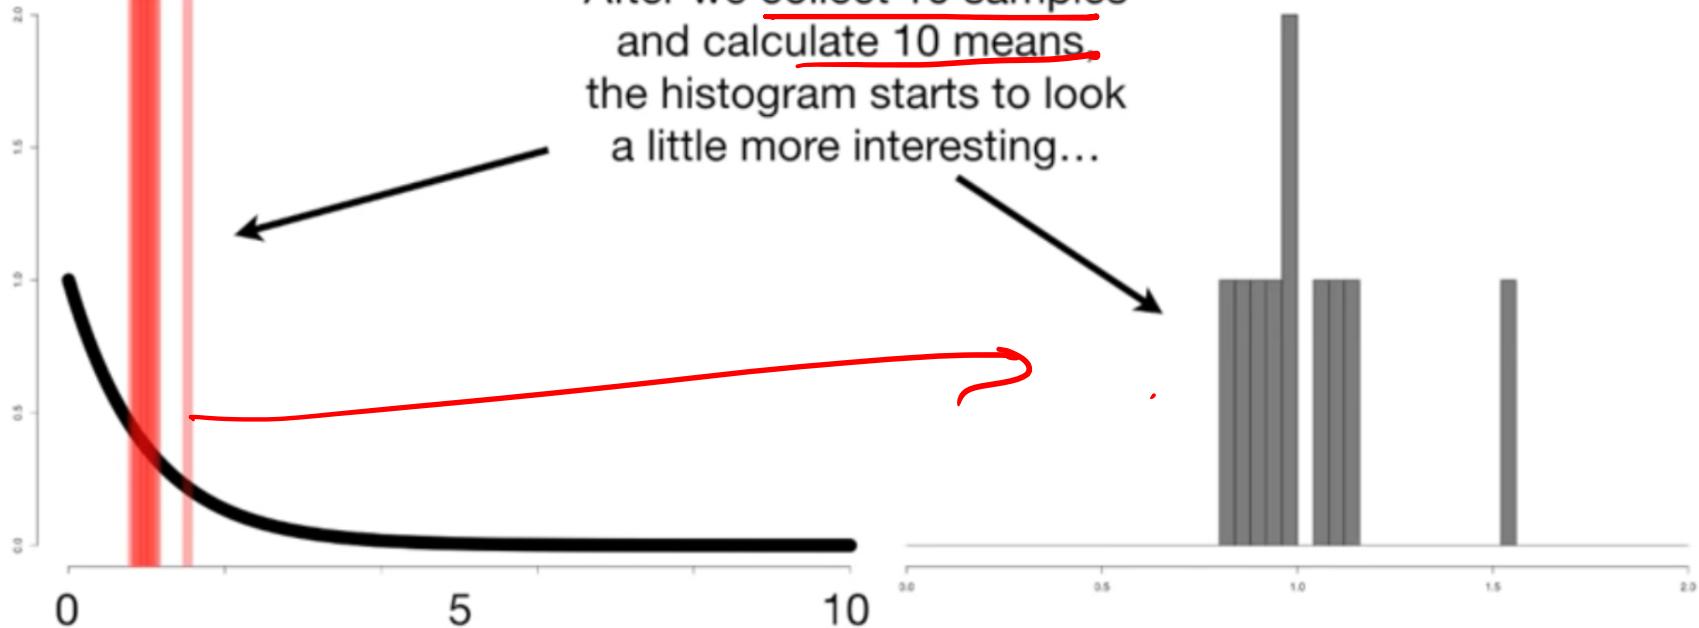

Central Limit Theorem

...and lastly, we can draw a histogram of that mean over here on the right.

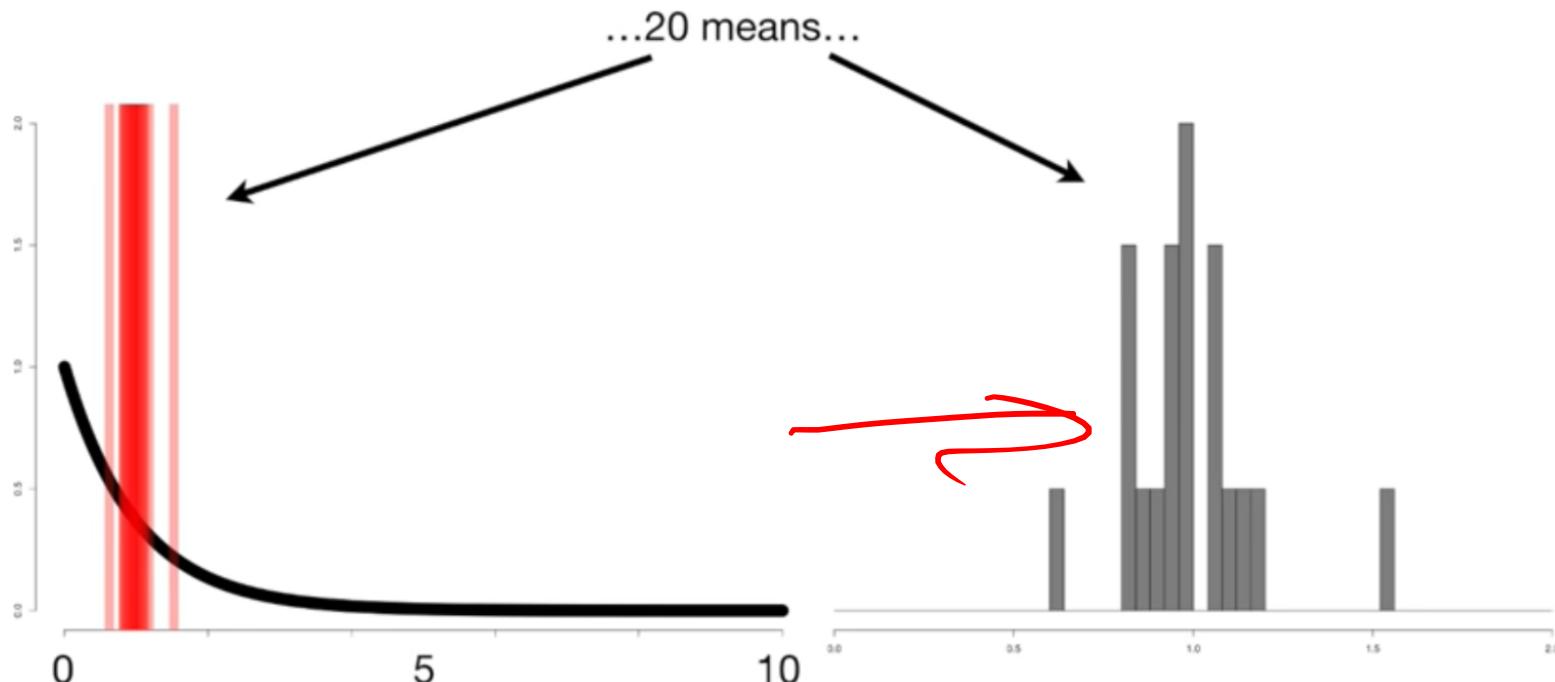

Central Limit Theorem

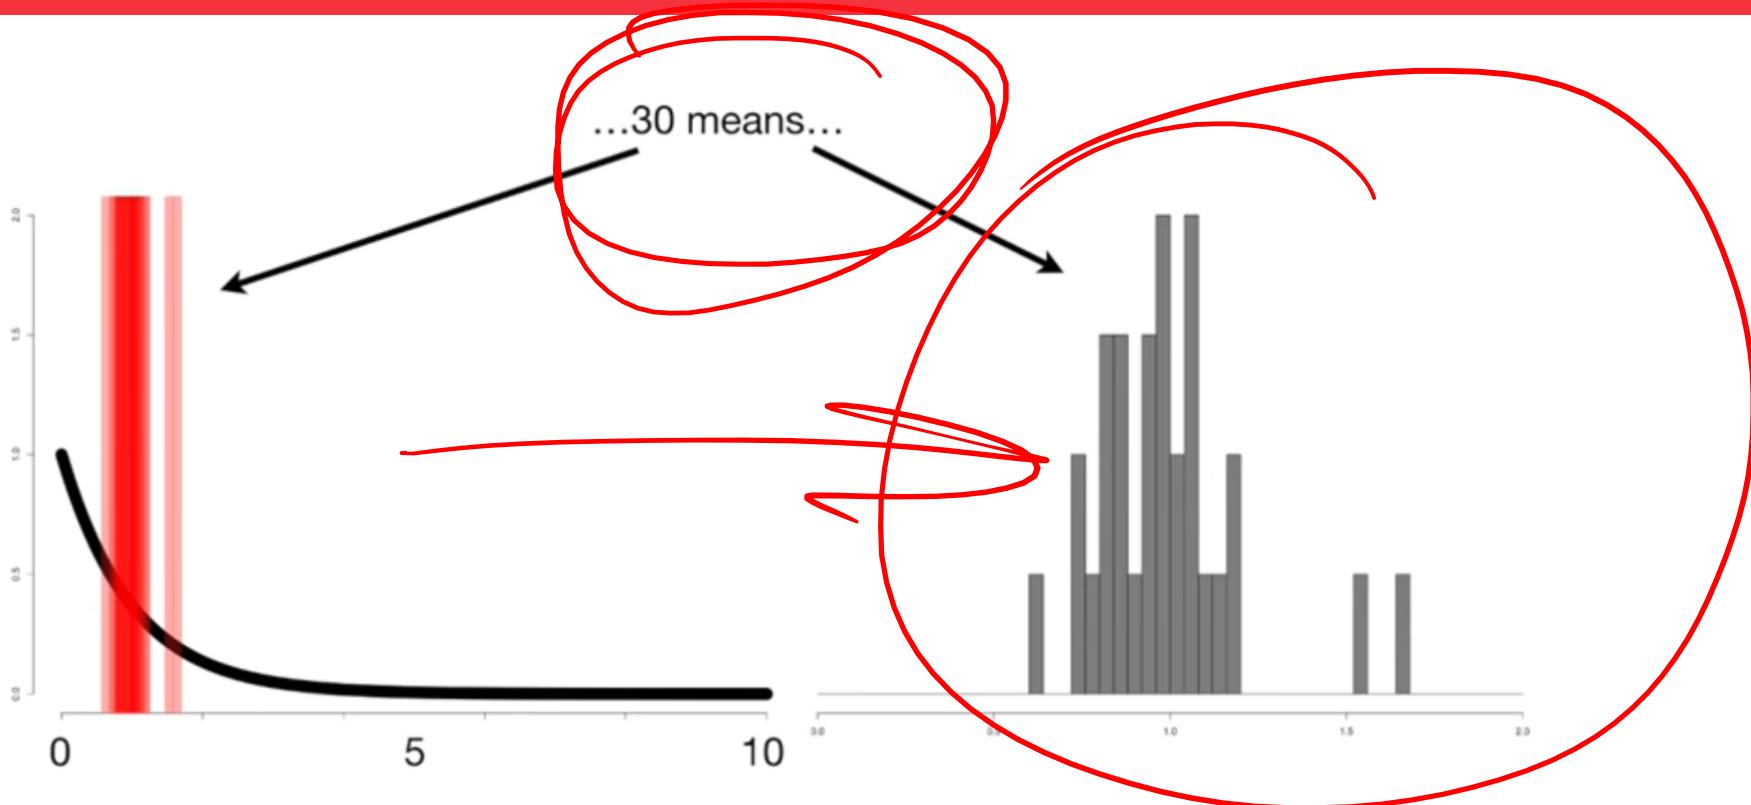

After we collect 10 samples
and calculate 10 means,
the histogram starts to look
a little more interesting...

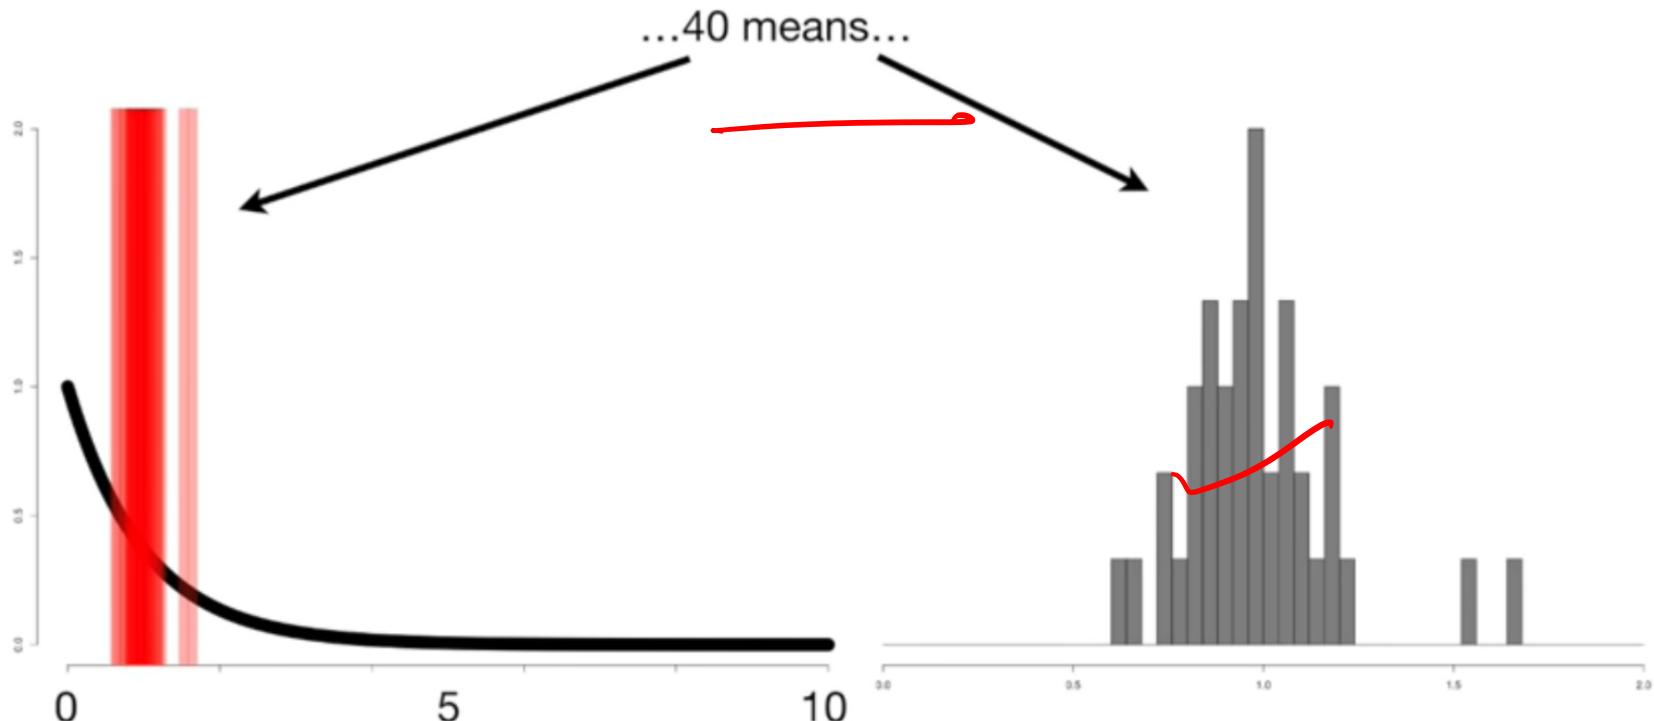

Central Limit Theorem

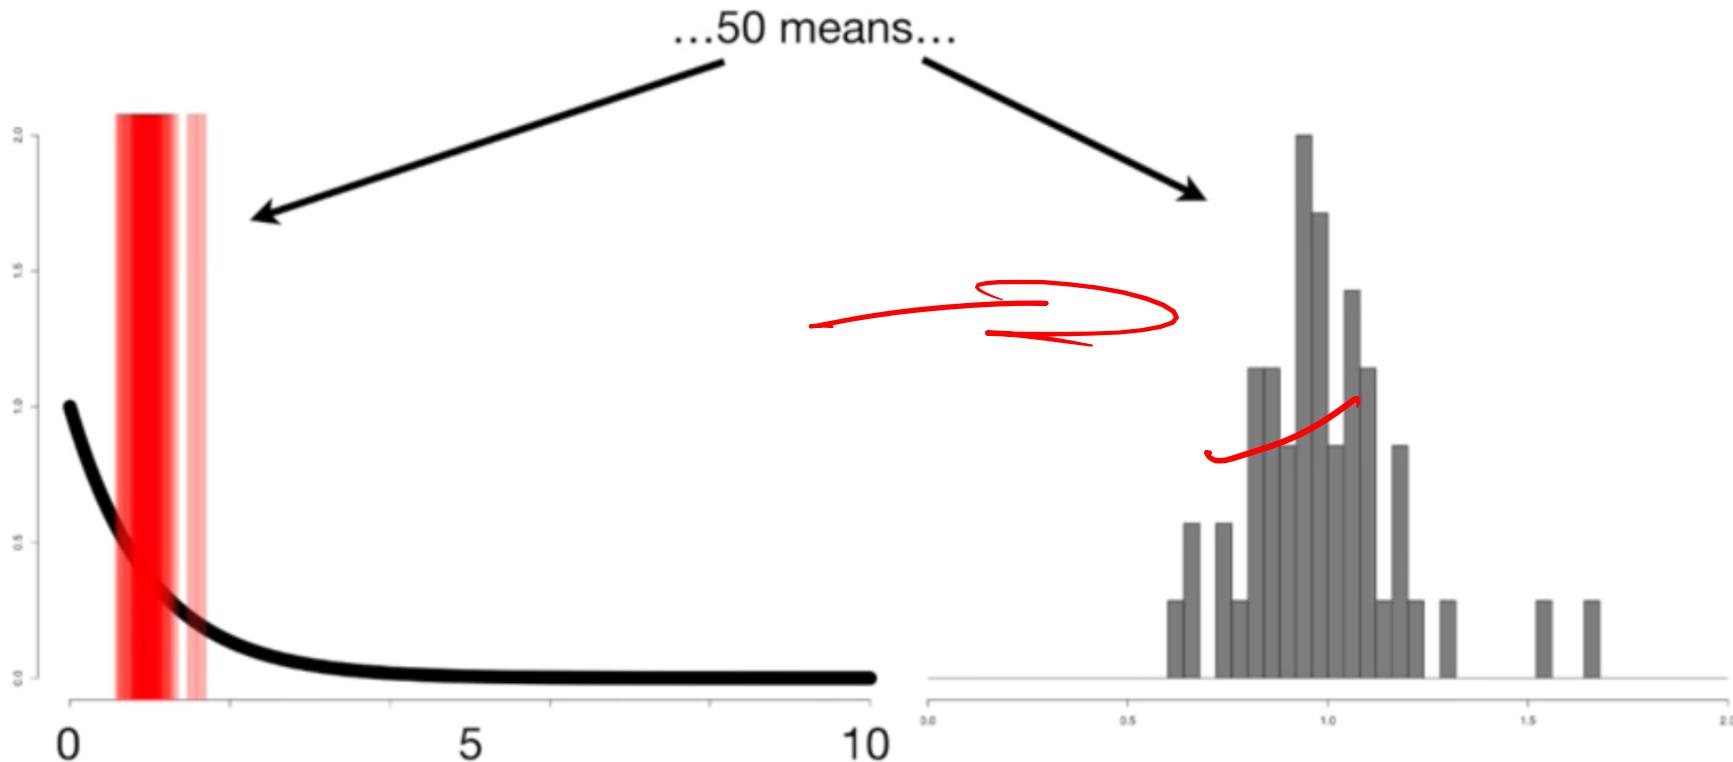

Central Limit Theorem

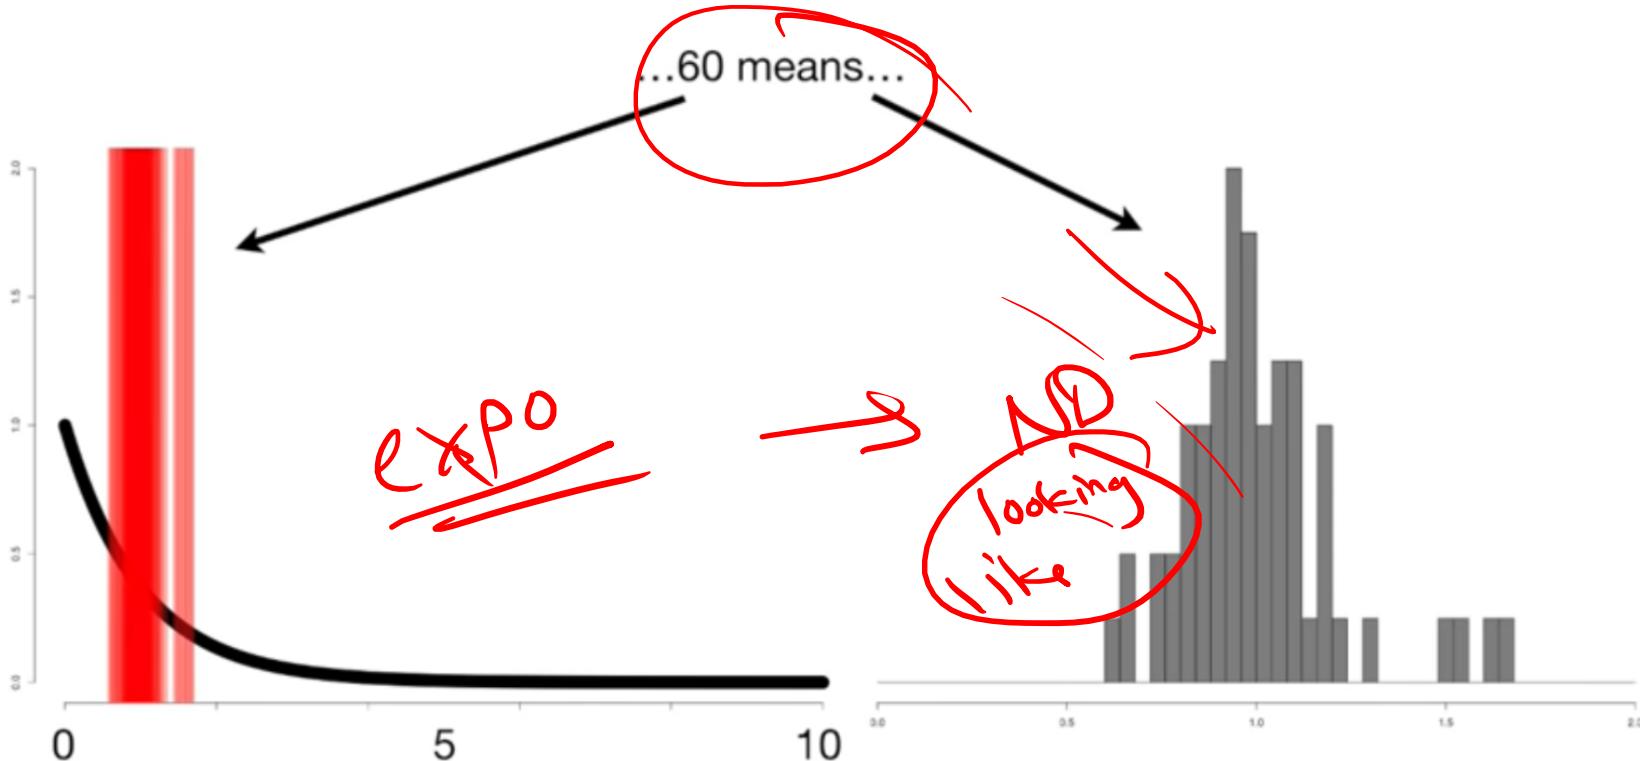

Central Limit Theorem

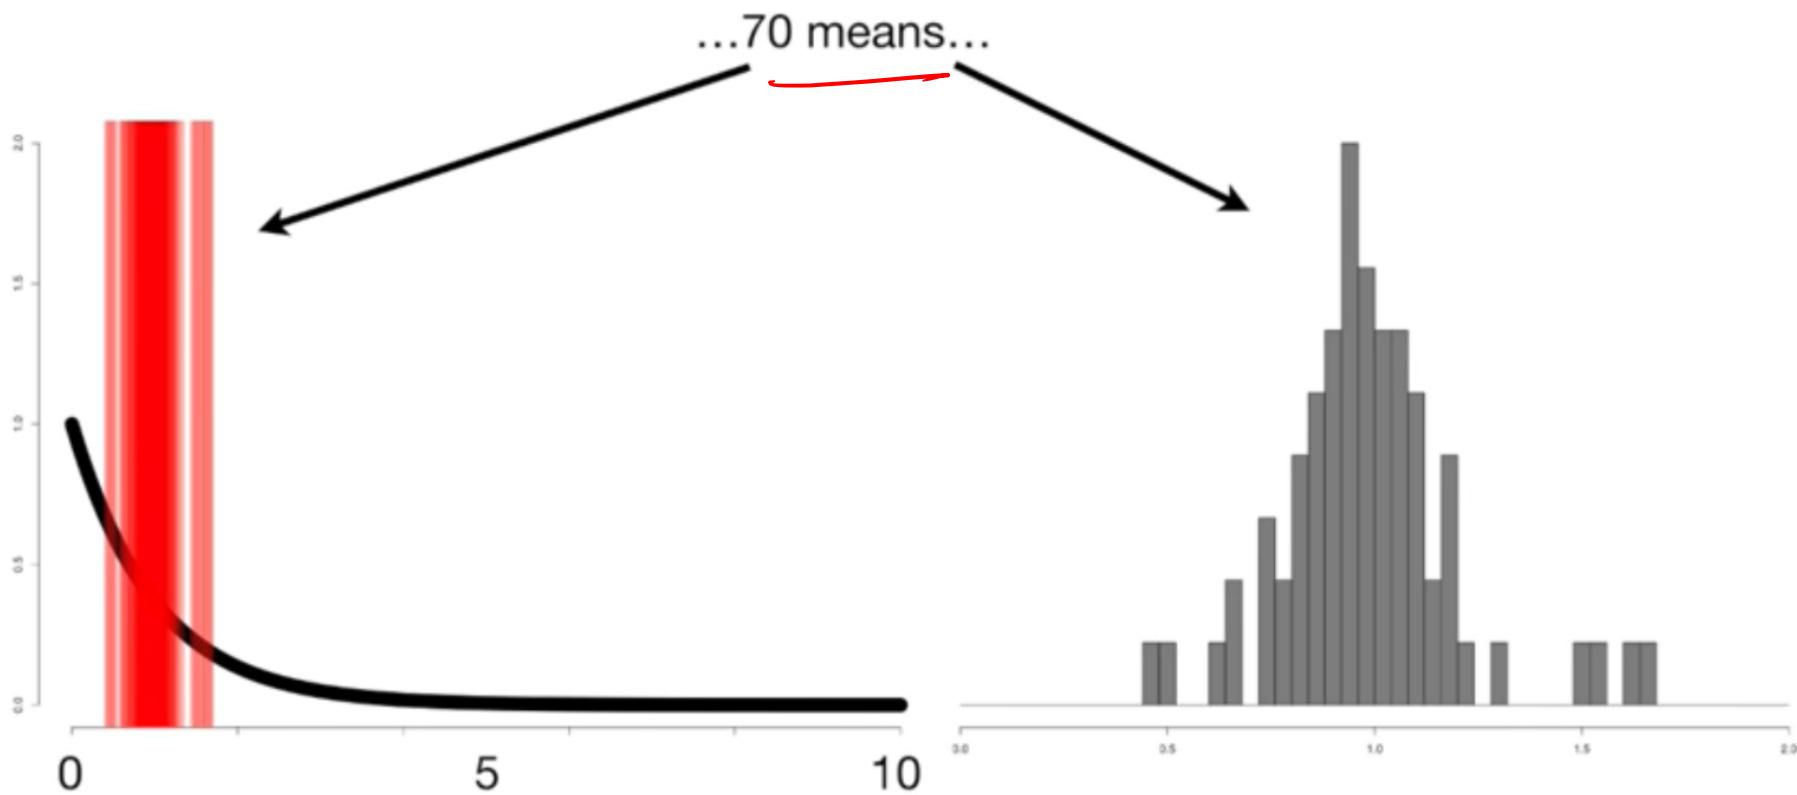

Central Limit Theorem

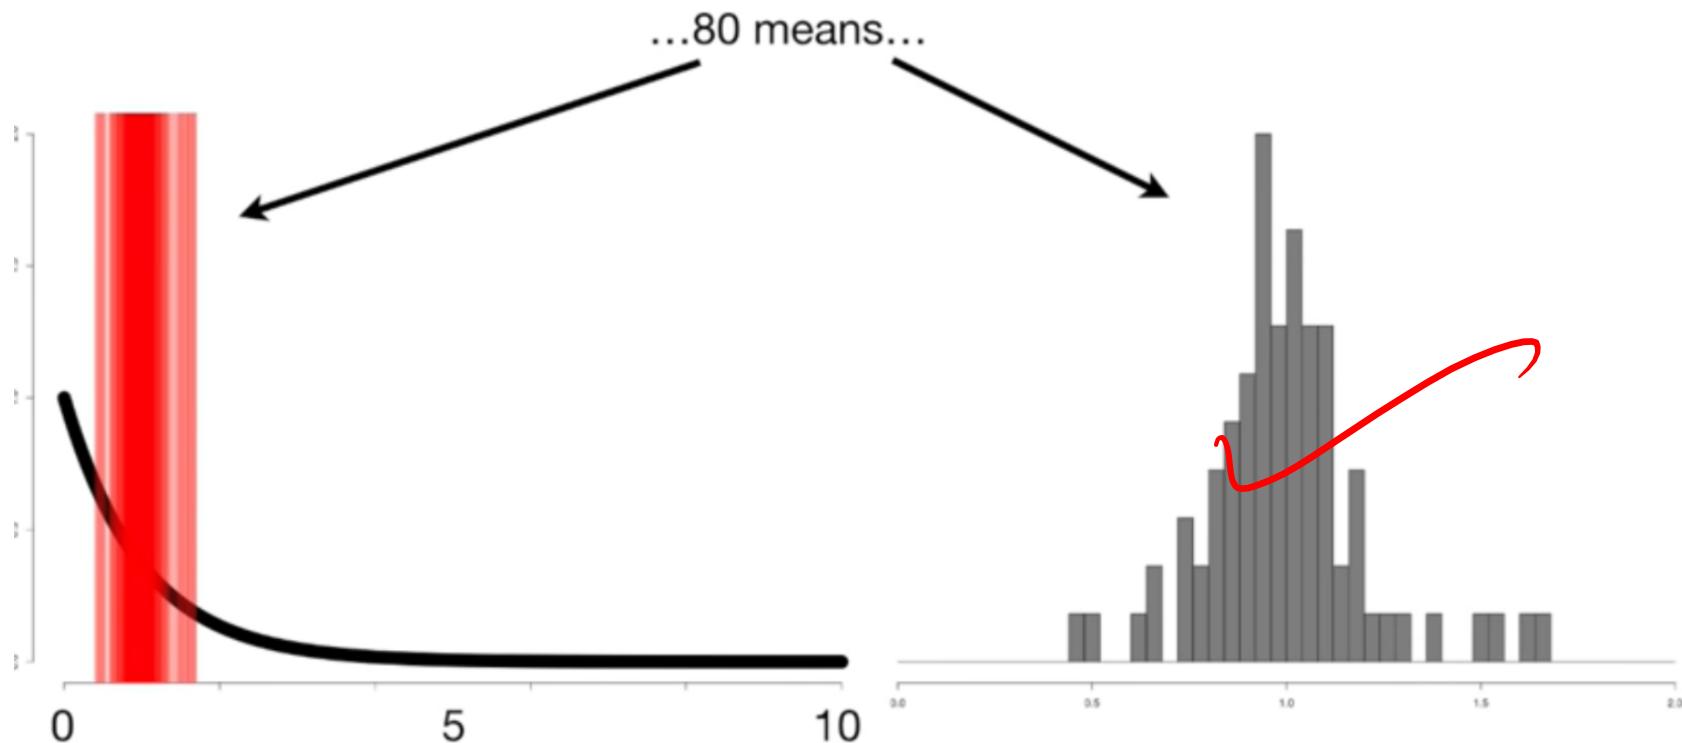

Central Limit Theorem

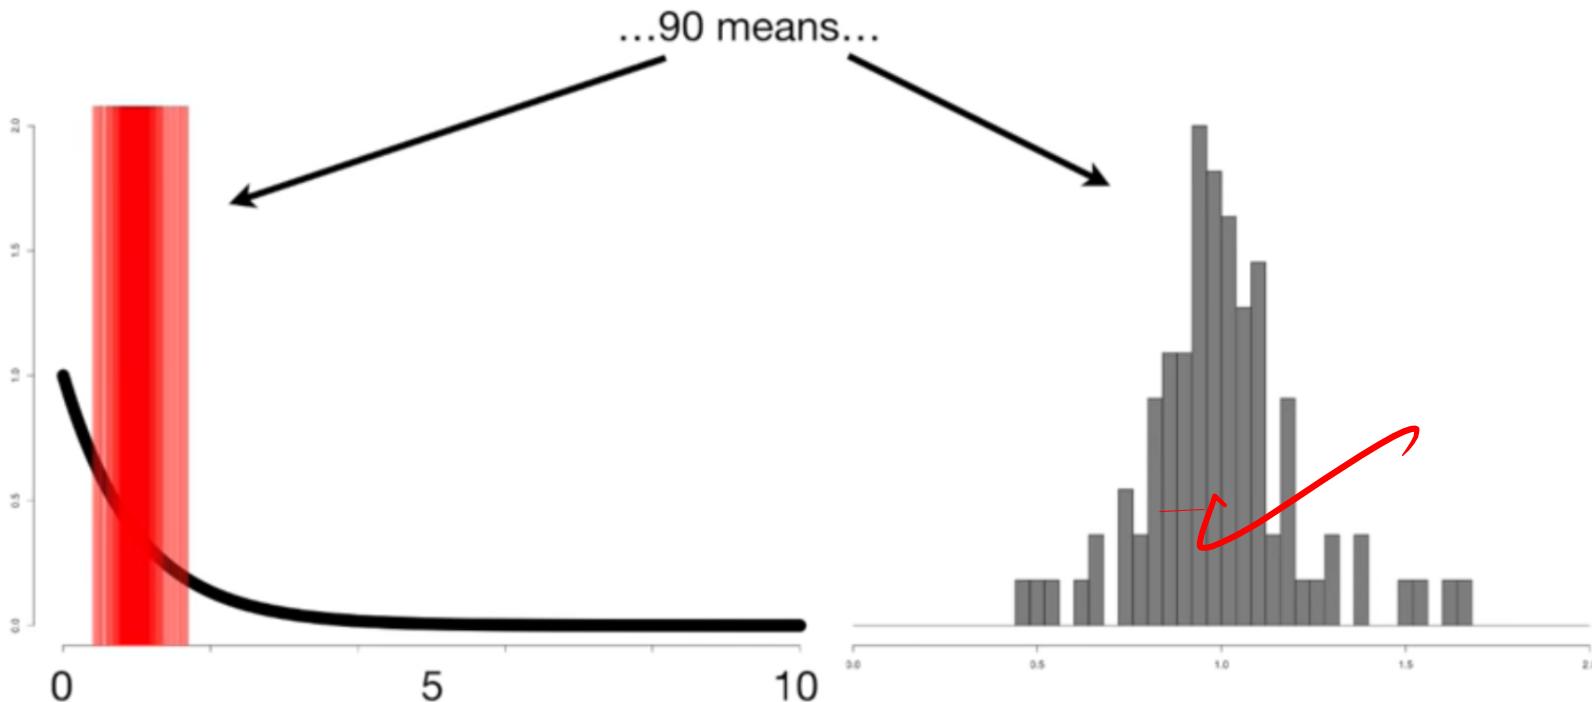

Central Limit Theorem

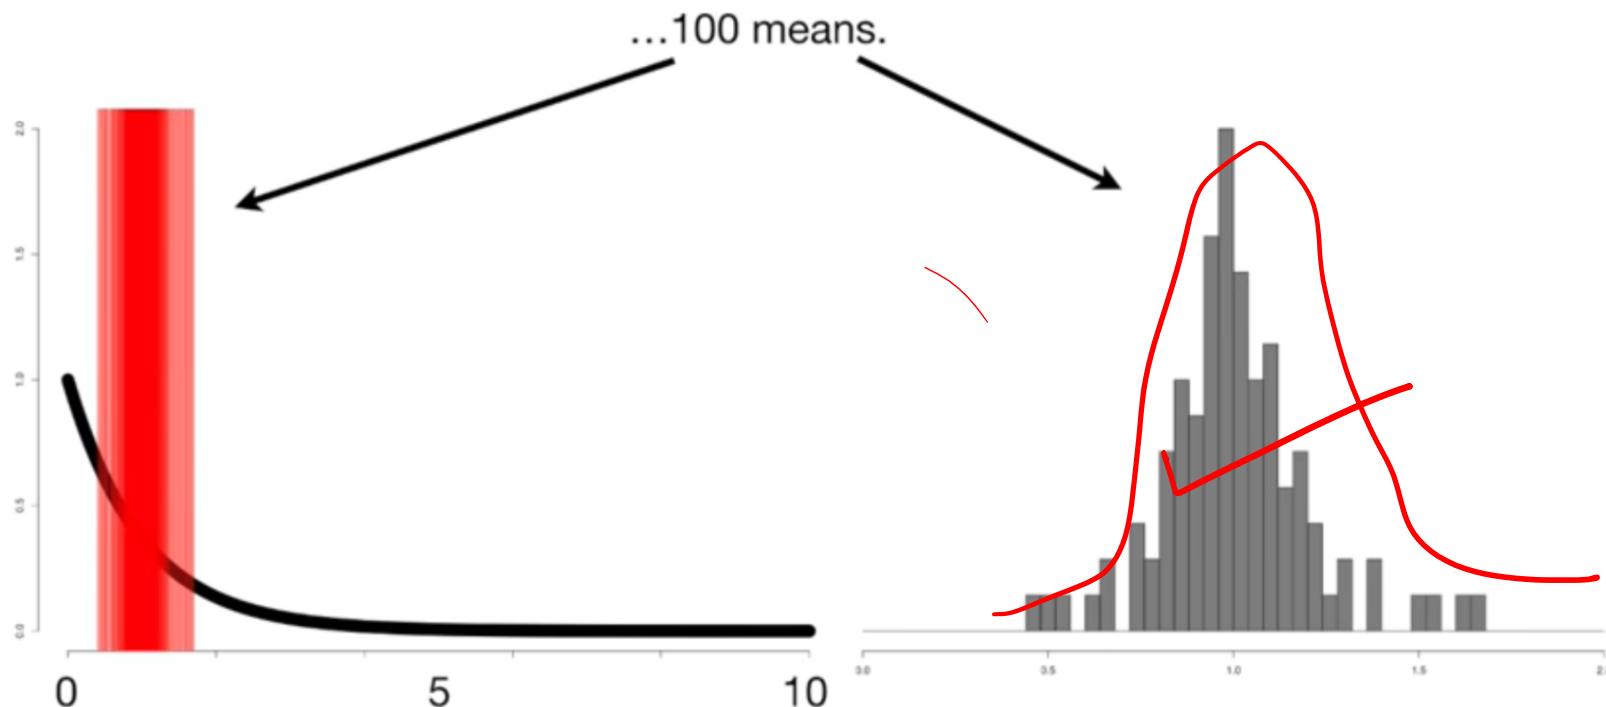

Central Limit Theorem

Central Limit Theorem

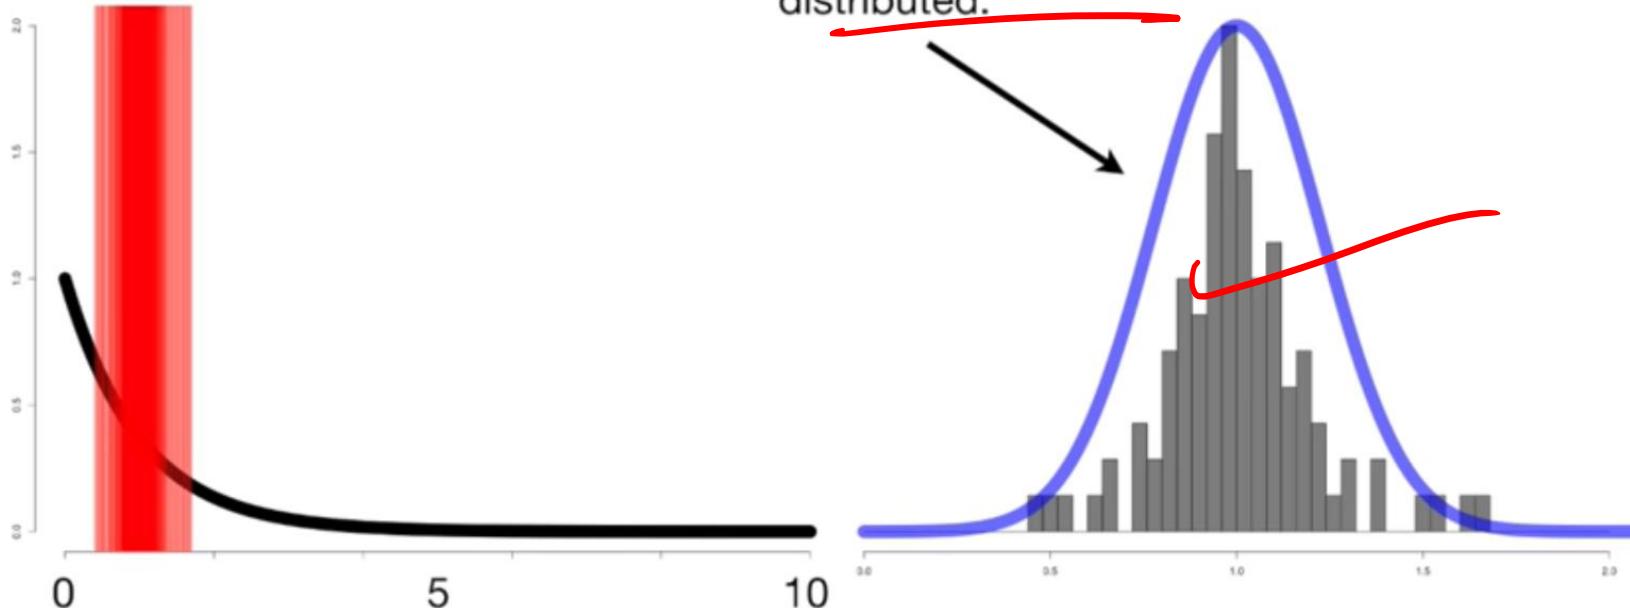

Central Limit Theorem

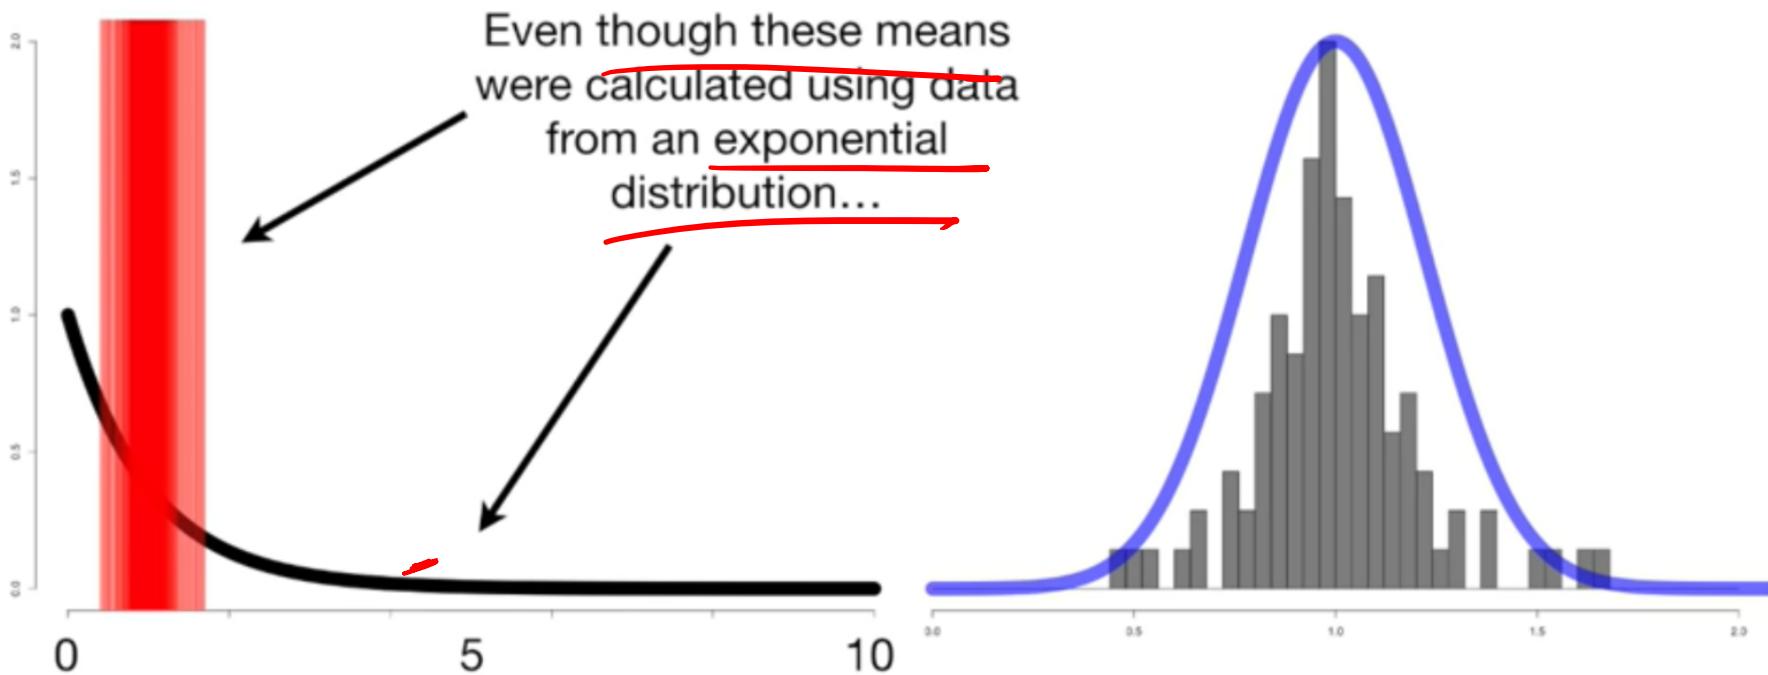

Central Limit Theorem

After adding 100 means to the histogram, we can see that they are normally distributed.

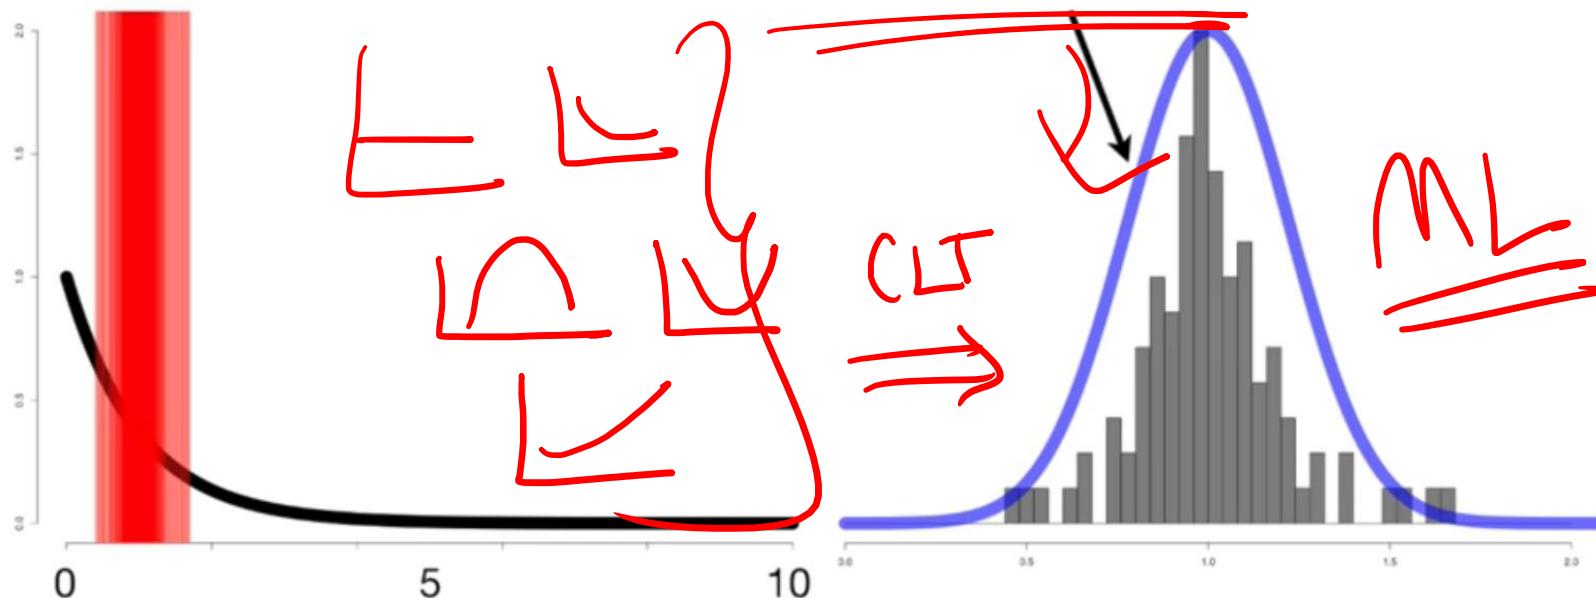

Central Limit Theorem

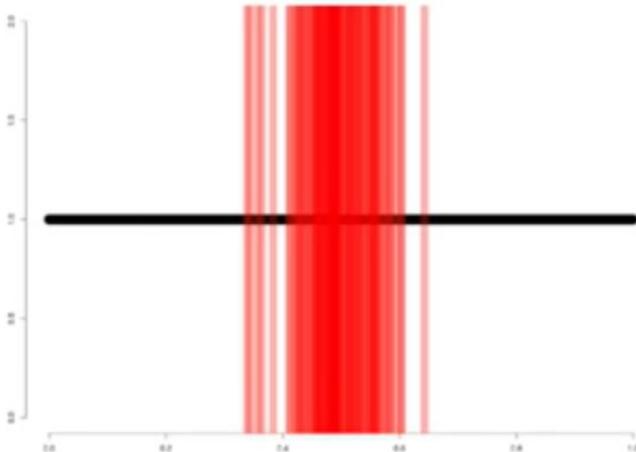

Central Limit Theorem

...the means themselves are not exponentially distributed. Instead, the **means are normally distributed.**

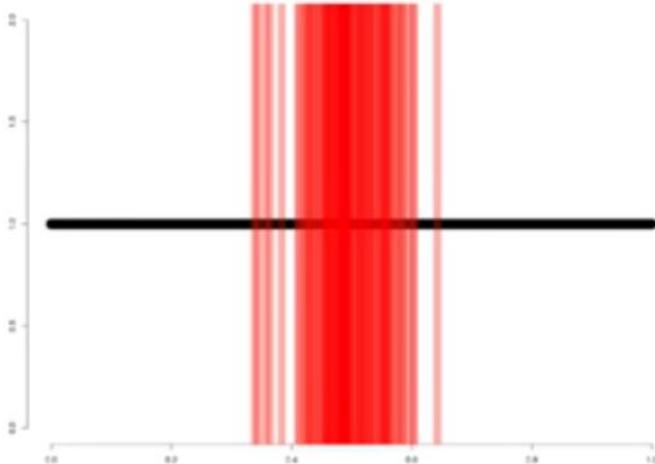

Central Limit Theorem

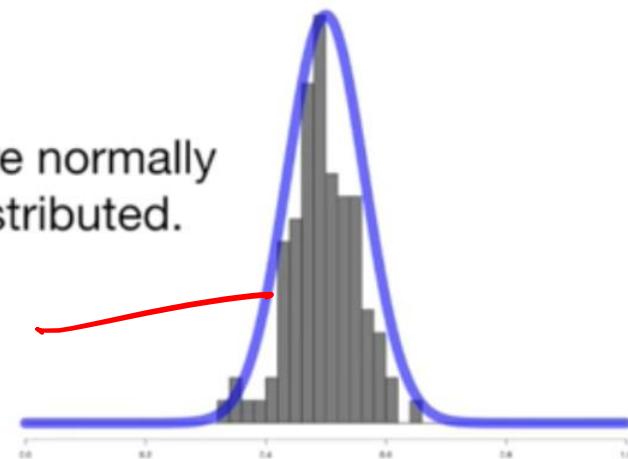

So far we have seen that means calculated from samples taken from a uniform distribution...

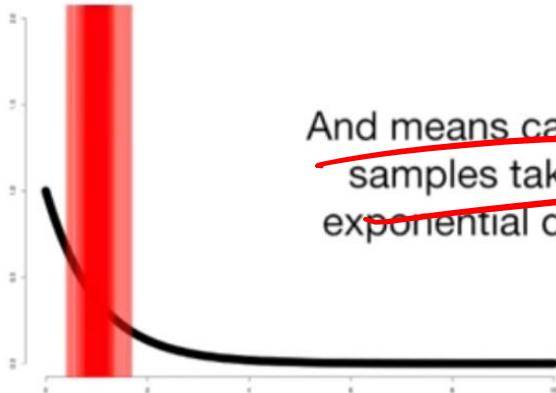

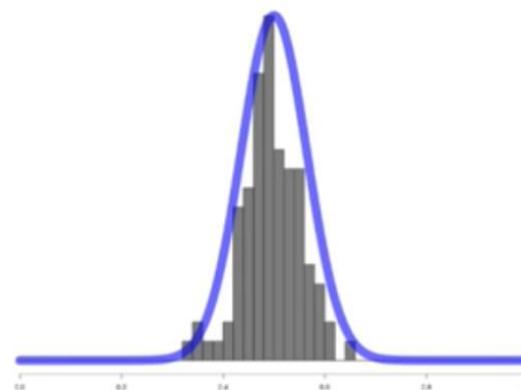

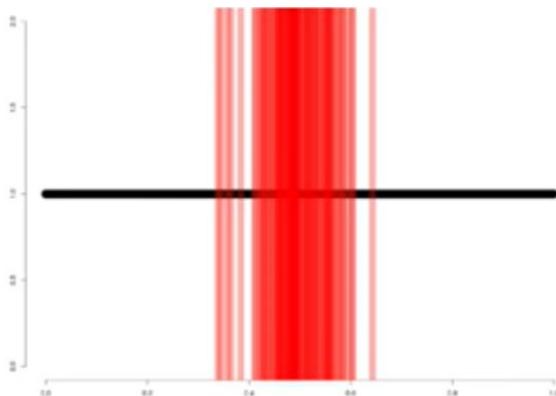

Central Limit Theorem

...are normally distributed.

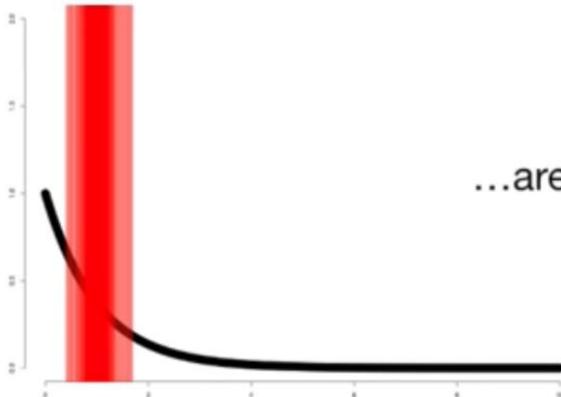

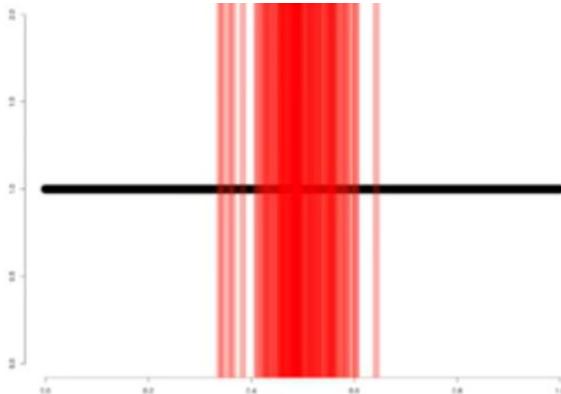

Central Limit Theorem

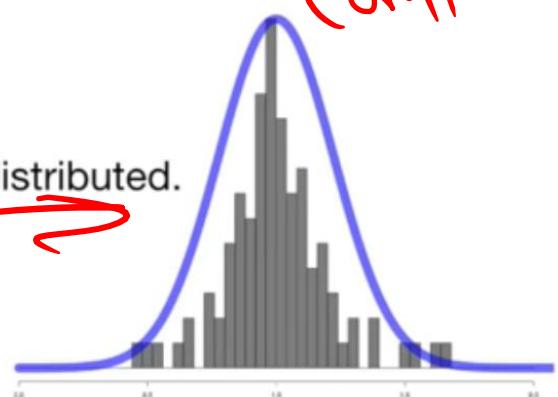

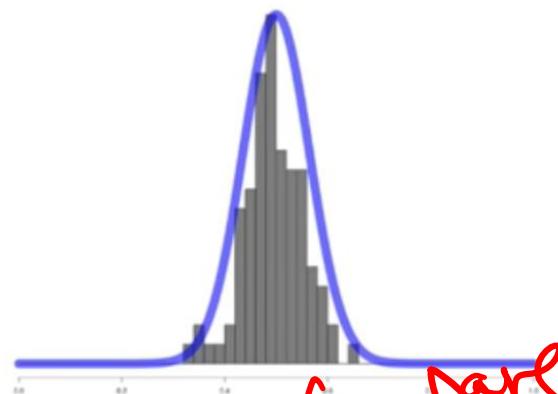

And means calculated from
samples taken from an
exponential distribution...

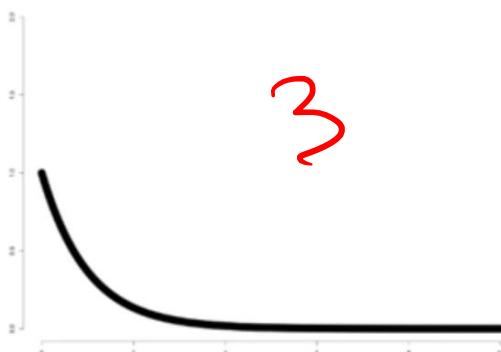

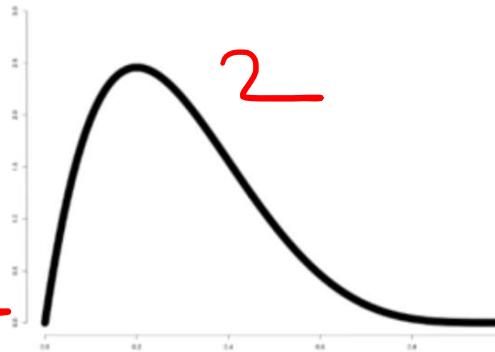

Central Limit Theorem

...are also normally distributed.

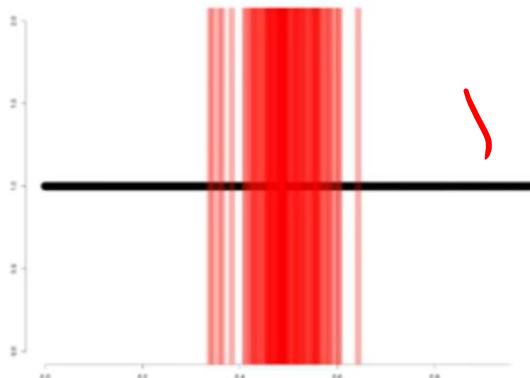

Central Limit Theorem

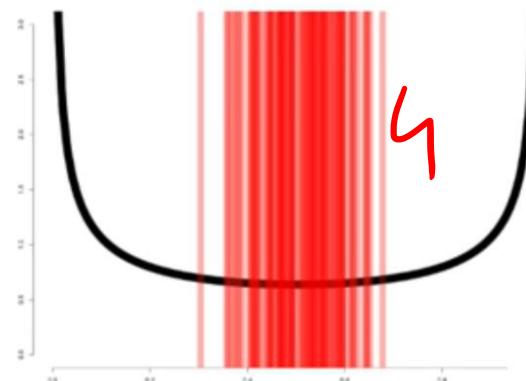

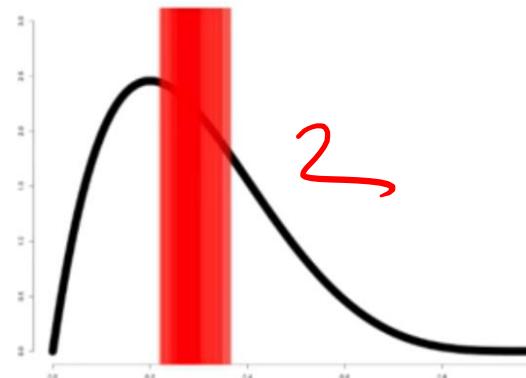

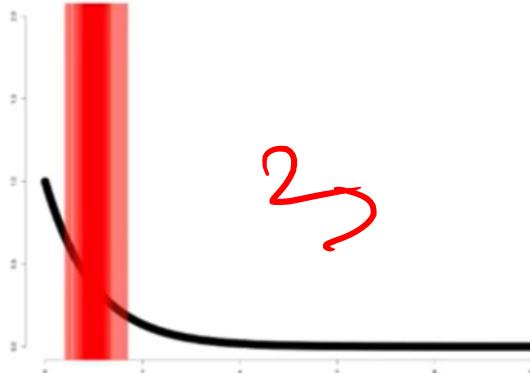

Well, it turns out that it
doesn't matter what
distribution you start
with...

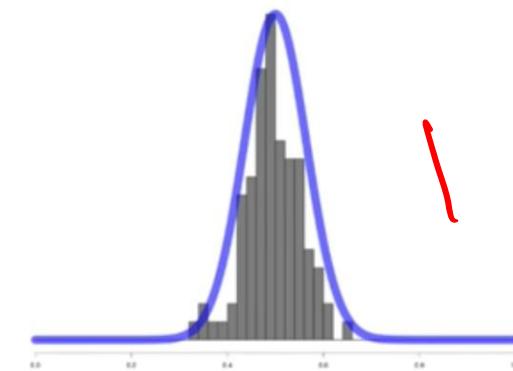

Central Limit Theorem

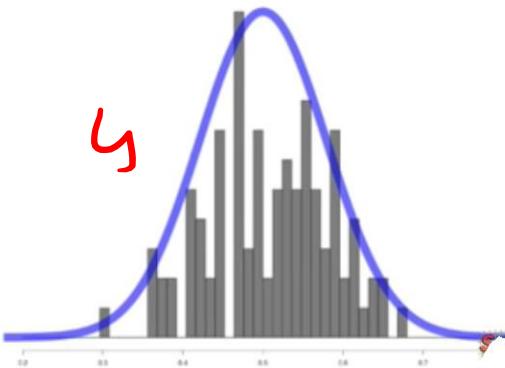

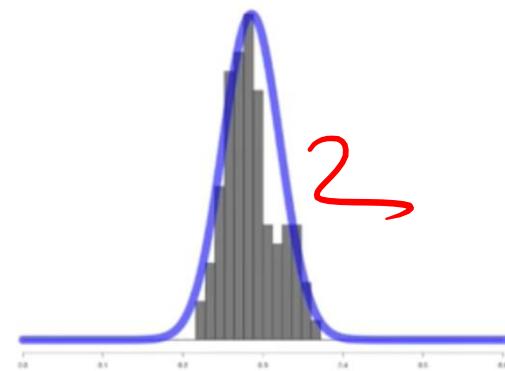

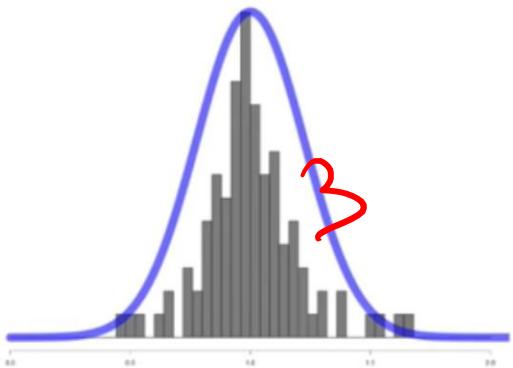

...if you collect
samples from those
distributions...

Central Limit Theorem

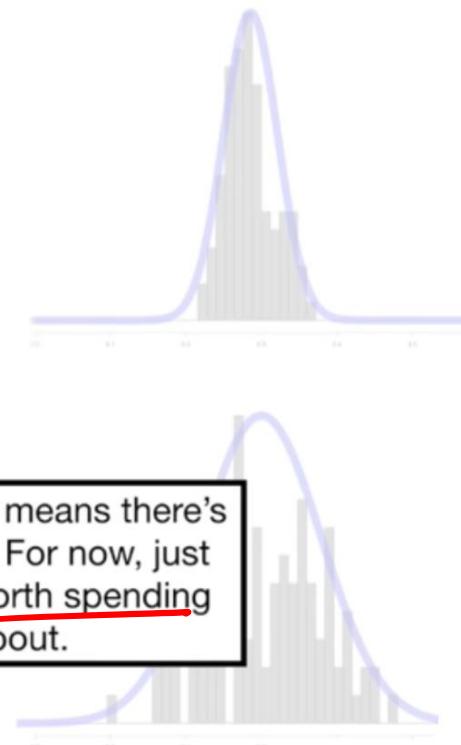

...then **the means will
be normally
distributed**.

Central Limit Theorem

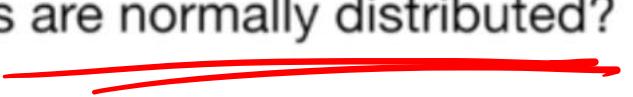

...then **the means will
be normally
distributed***

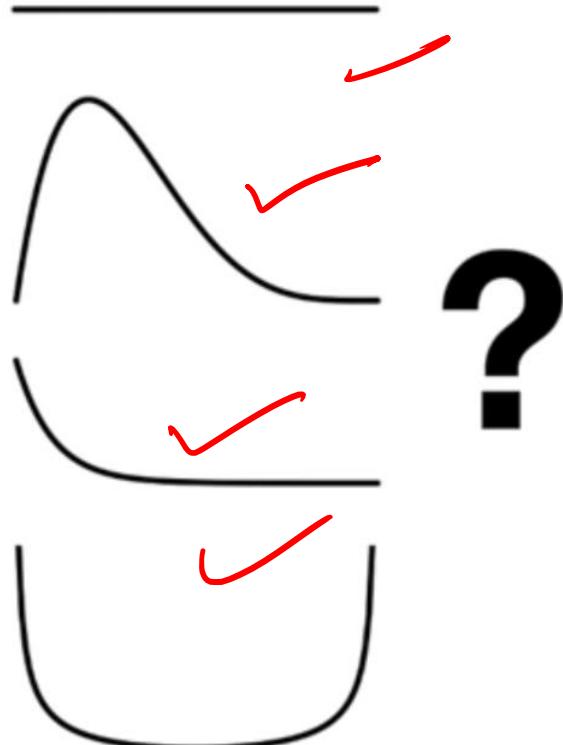

Yes, there's a little asterisk here that means there's some fine print that will come later. For now, just know it's really fine print and not worth spending too much time worrying about.

Cool!

But what are the practical implications of knowing
that means are normally distributed?

Central Limit Theorem

When we do an experiment, we
don't always know what
distribution our data comes from.

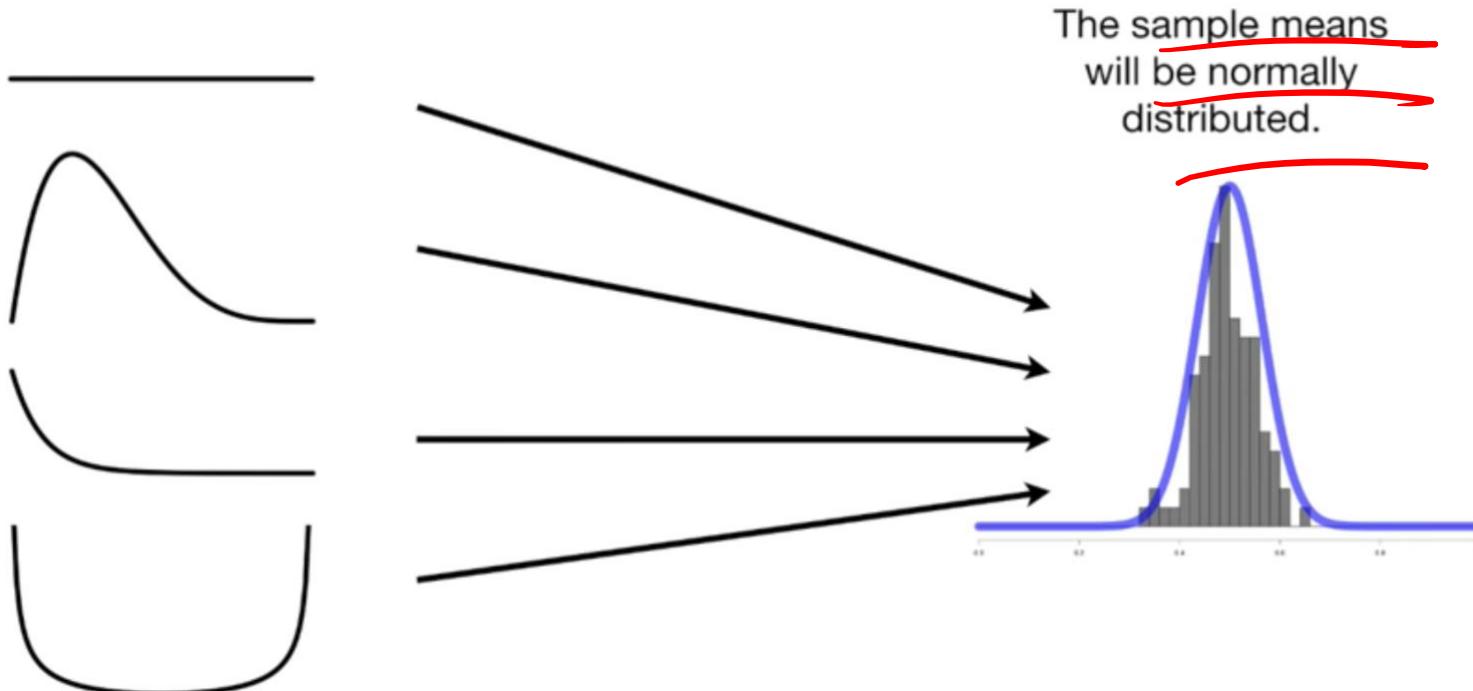

Central Limit Theorem

upGrad

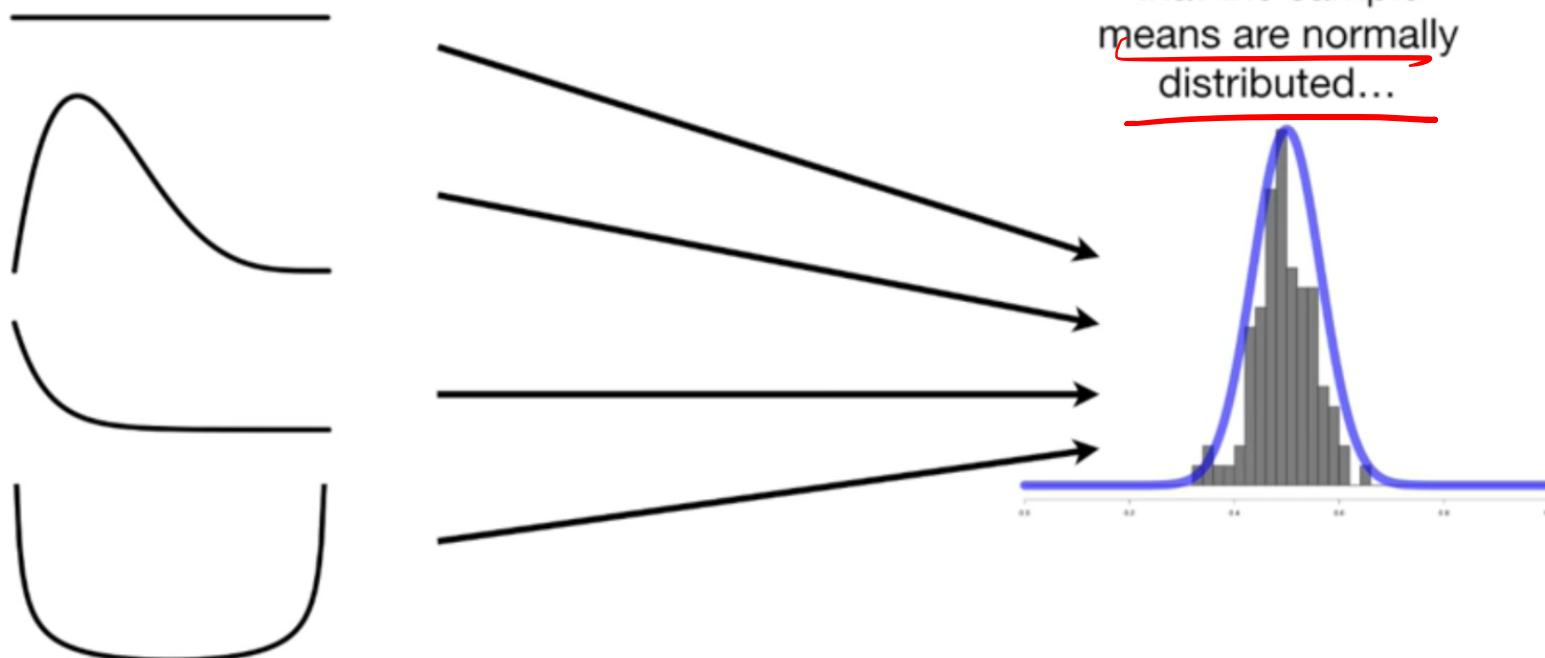

To this, The Central Limit Theorem
says, "Who Cares???"

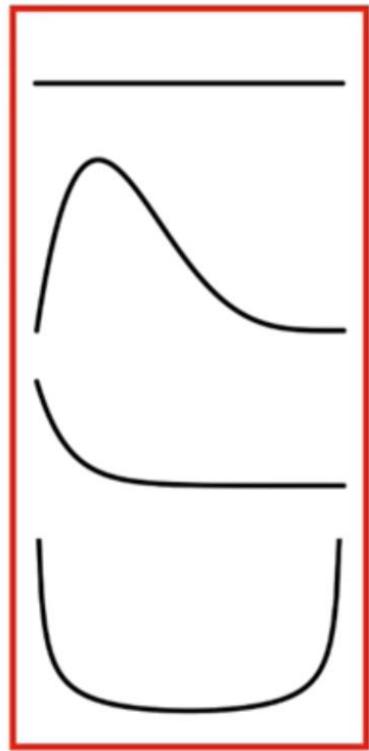

Central Limit Theorem

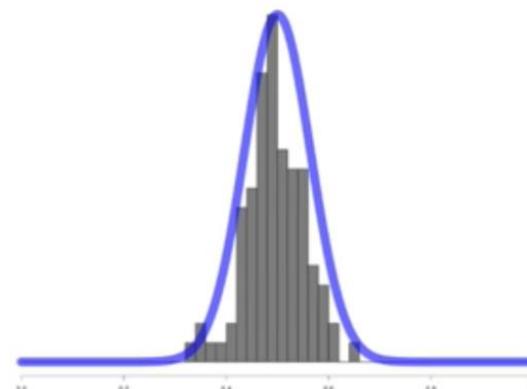

Central Limit Theorem

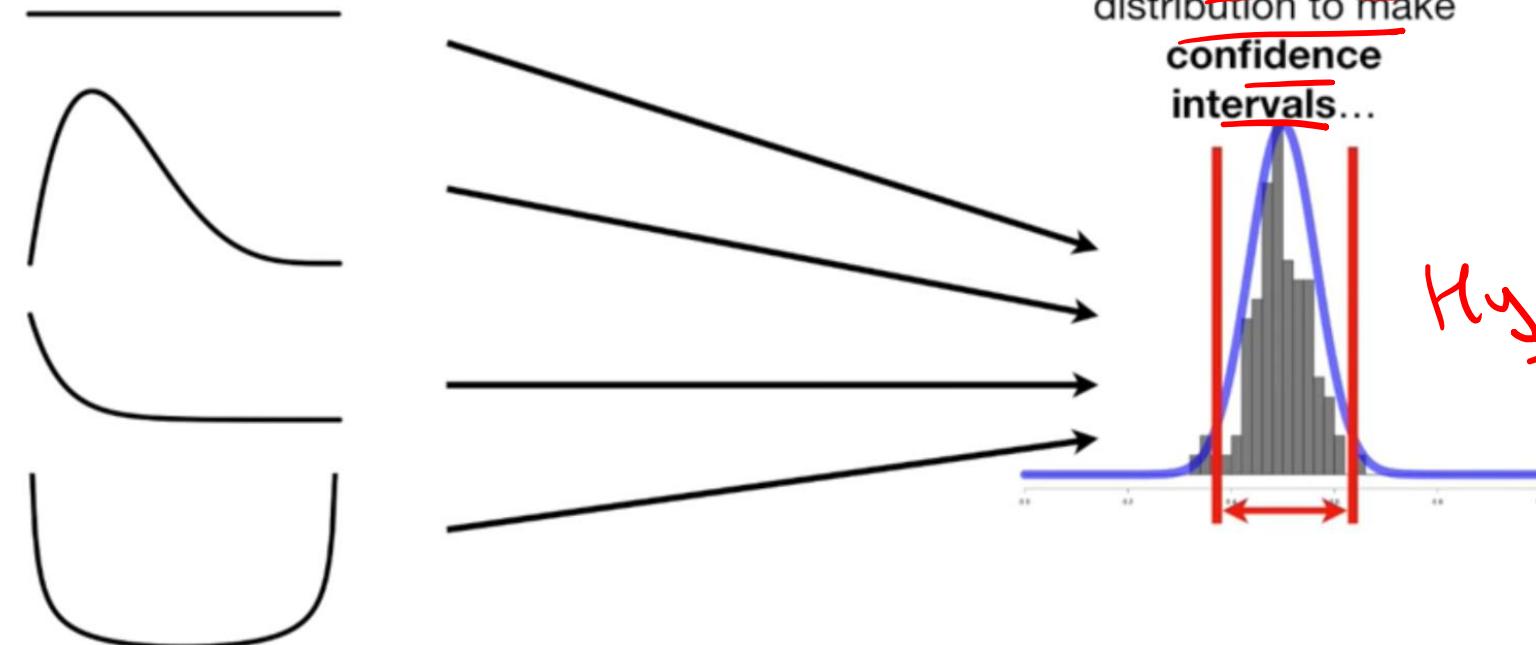

Central Limit Theorem

...we don't need to worry
too much about the
distribution that the
samples came from.

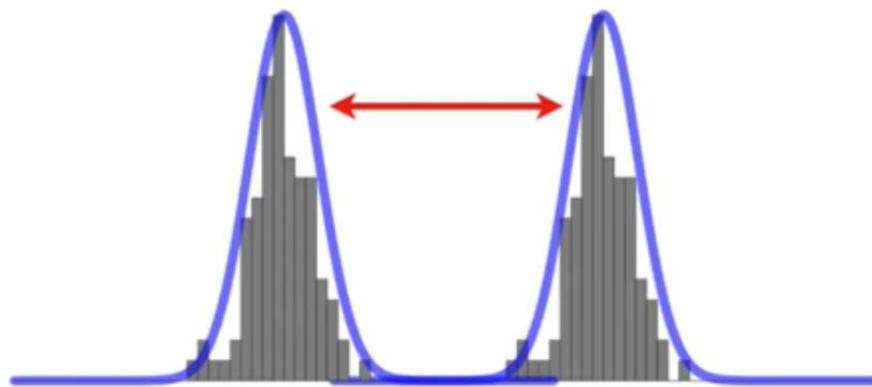

Central Limit Theorem

Central Limit Theorem

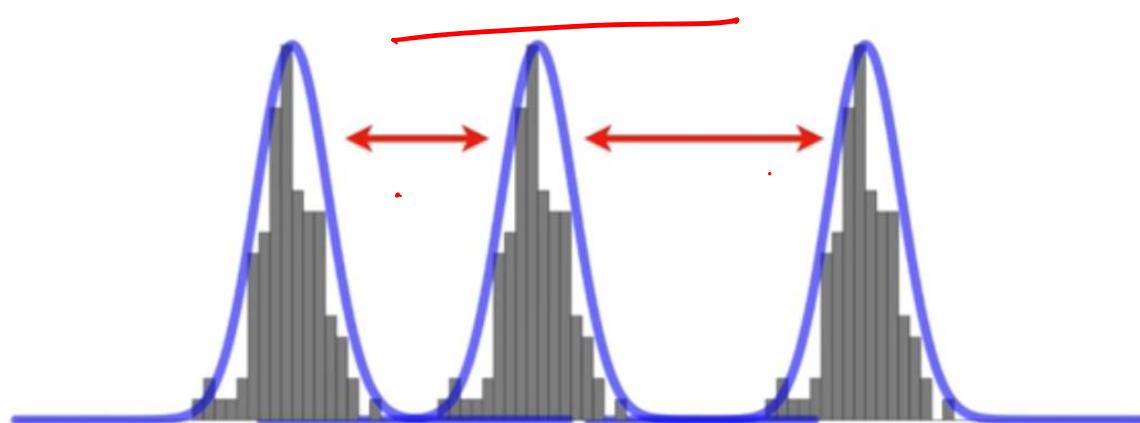

...do **t-tests**, where we ask if
there is a difference between
the means from two samples...

Central Limit Theorem

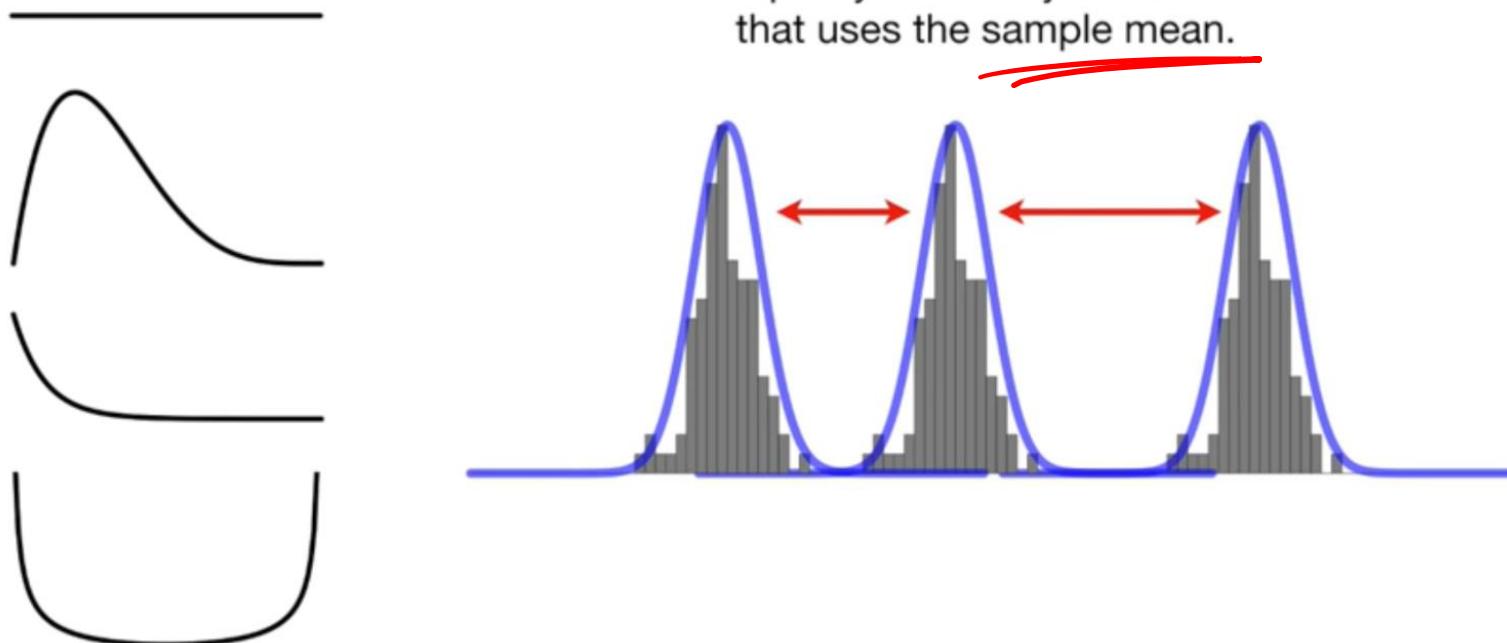

upGrad

...and **ANOVA**, where we ask if there is a difference among the means from three or more samples...

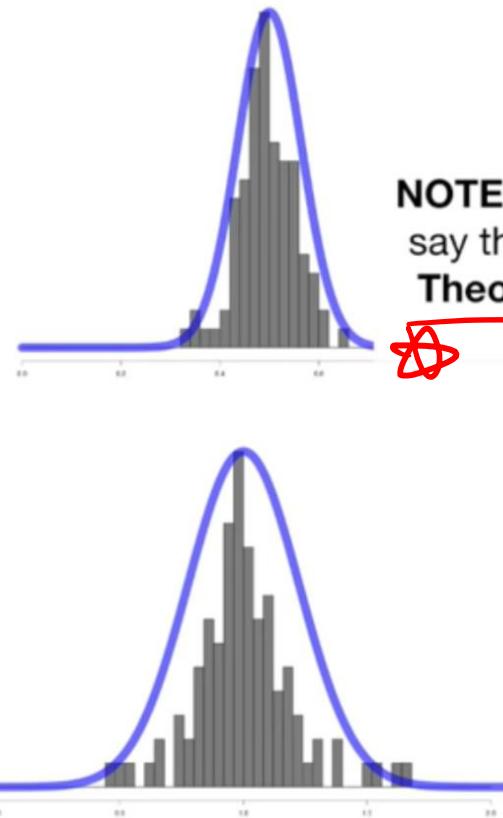

Central Limit Theorem

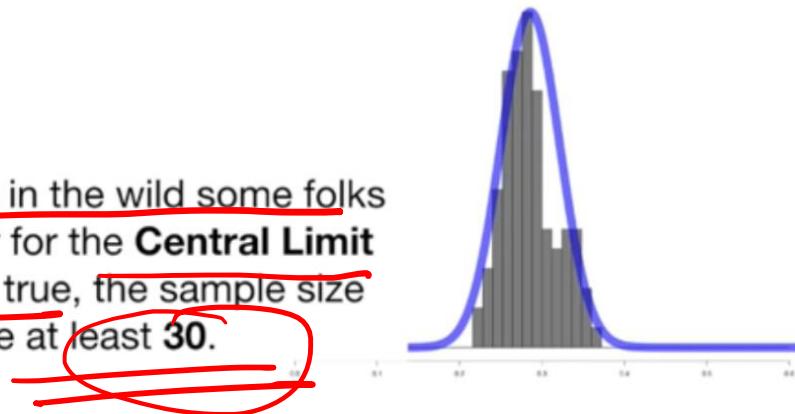

...and pretty much any statistical test
that uses the sample mean.

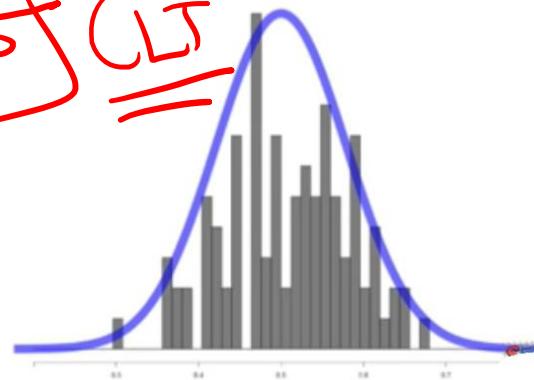

Central Limit Theorem

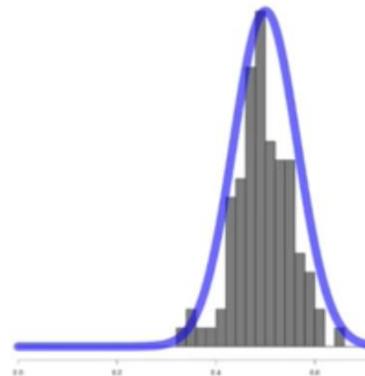

NOTE: Out there in the wild some folks say that in order for the **Central Limit Theorem** to be true, the sample size must be at least 30.

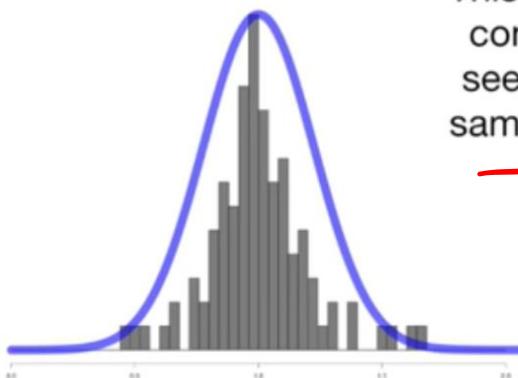

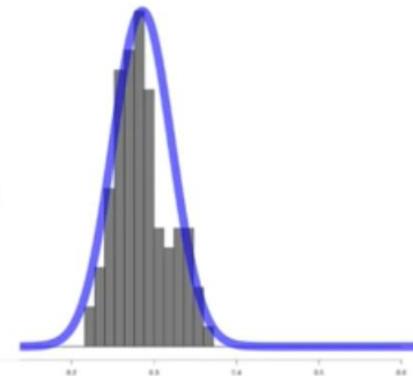

$n = 30$ CLT

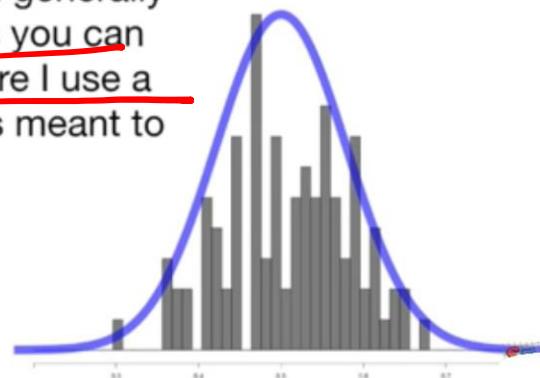

Central Limit Theorem

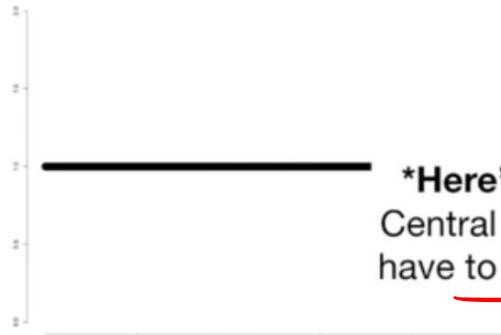

NOTE: Out there in the wild some folks say that in order for the **Central Limit Theorem** to be true, the sample size must be at least **30**.

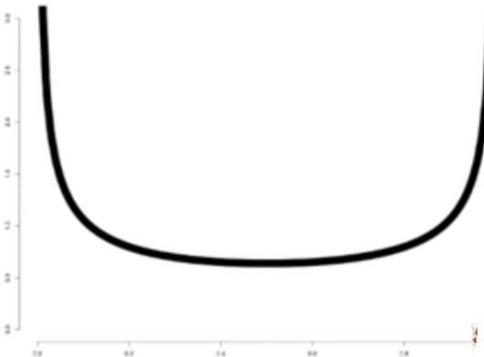

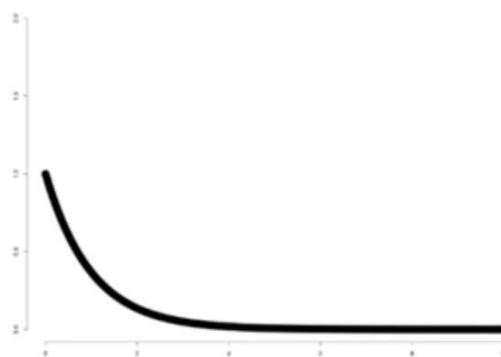

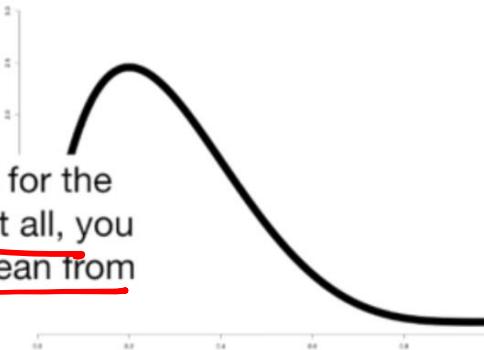

This is just a rule of thumb and generally considered safe. However, as you can see in the examples here where I use a sample size of **20**, the rule was meant to be broken.

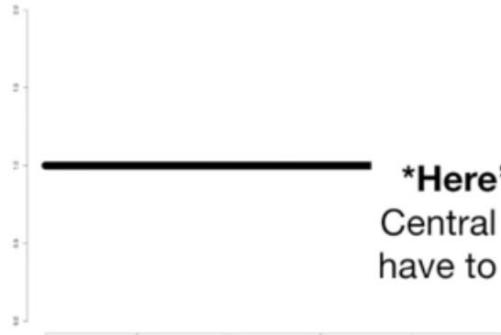

Central Limit Theorem

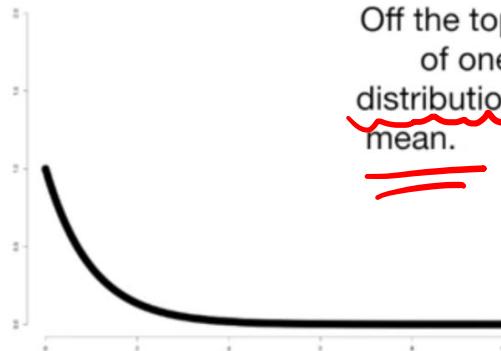

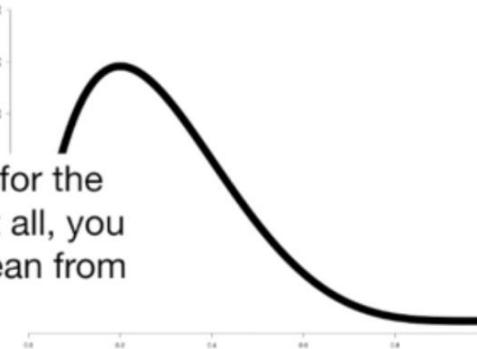

*Here's the fine print: In order for the Central Limit Theorem to work at all, you have to be able to calculate a mean from your sample.

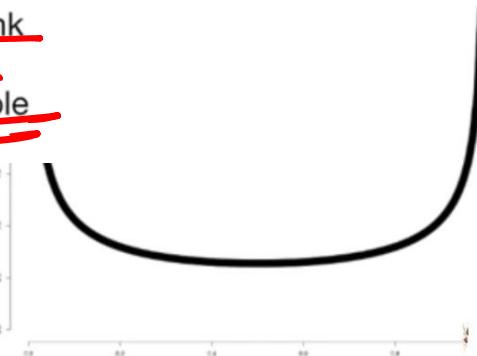

Central Limit Theorem

*Here's the fine print: In order for the Central Limit Theorem to work at all, you have to be able to calculate a mean from your sample.

Off the top of my head, I can only think of one distribution, the Cauchy distribution, that doesn't have a sample mean.

When you have a test that can say "Yes" or "No" (such as a medical test), you have to think:

- It could be **wrong** when it says "Yes".
- It could be **wrong** when it says "No".

It is like being told you **did** something when you **didn't!**

Or you didn't do it when you really did.

- They each have a special name: "**False Positive**" and "**False Negative**":

	They say you did	They say you didn't
You really did	<i>They are right!</i>	"False Negative"
You really didn't	"False Positive"	<i>They are right!</i>

Example

- Hunter says she is itchy. There is a test for Allergy to Cats, but this test is not always right:
 - For people that **really do** have the allergy, the test says "Yes" **80%** of the time
 - For people that **do not** have the allergy, the test says "Yes" **10%** of the time ("false positive")

	Test says "Yes"	Test says "No"
Have allergy	80%	20% "False Negative"
Don't have it	10% "False Positive"	90%

- If 1% of the population have the allergy, and Hunter's test says "Yes", what are the chances that Hunter really has the allergy?
- There are three different ways to solve this:
 - "Imagine a 1000",
 - "Tree Diagrams" or
 - "Bayes' Theorem"

Solution 3: Bayes' Theorem

upGrad

- Bayes' Theorem has a special formula for this kind of thing:

$$P(A|B) = \frac{P(A)P(B|A)}{P(A)P(B|A) + P(\text{not } A)P(B|\text{not } A)}$$

where:

- P means "Probability of"
- $|$ means "given that"
- A in this case is "actually has the allergy"
- B in this case is "test says Yes"

- So:
- **$P(A|B)$** means "The probability that Hunter actually has the allergy given that the test says Yes"
- **$P(B|A)$** means "The probability that the test says Yes given that Hunter actually has the allergy"

- **P(A|B)** means "The probability that Hunter actually has the allergy given that the test says Yes"
- **P(B|A)** means "The probability that the test says Yes given that Hunter actually has the allergy"

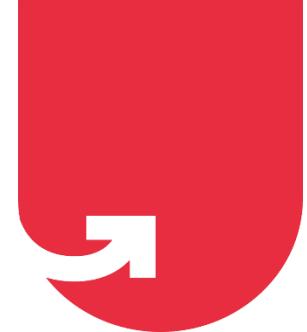

To be clearer, let's change A to **has** (actually has allergy) and B to **Yes** (test says yes):

$$P(\text{has}|\text{Yes}) = \frac{P(\text{has})P(\text{Yes}|\text{has})}{P(\text{has})P(\text{Yes}|\text{has}) + P(\text{not has})P(\text{Yes}|\text{not has})}$$

And put in the numbers:

$$\begin{aligned} P(\text{has}|\text{yes}) &= \frac{0.01 \times 0.8}{0.01 \times 0.8 + 0.99 \times 0.1} \\ &= 0.0748... \end{aligned}$$

Which is about **7%**

Thank You!
